SimpleITK is a simplified, open source, interface to the Insight Toolkit (ITK), a C++ open source image analysis toolkit which is widely used in academia and industry. SimpleITK is available for eight programming languages including C++, Python, R, Java, C#, Lua, Ruby, and TCL. Binary distributions of SimpleITK are currently available for all three major operating systems (Linux, OS X, and Windows).
SimpleITK is a simplified programming interface to the algorithms and data structures of the Insight Toolkit (ITK). It supports bindings for multiple programming languages including C++, Python, Java, C#, Lua, Ruby and TCL. These bindings enable scientists to develop image analysis workflows in the programming language they are most familiar with. The toolkit supports more than 15 different image file formats, provides over 280 image analysis filters, and implements a unified interface to the ITK intensity-based registration framework.

1.1 History

SimpleITK was created as part of a concerted effort to simplify the use of the Insight Toolkit, making it more accessible to a wider audience.

The initial funding for the toolkit was provided by the United States National Library of Medicine (NLM) under the American Recovery and Reinvestment Act (ARRA), with the initial version of the toolkit developed as a collaboration between The Mayo Clinic, Kitware Inc, The University of Iowa and NLM’s intramural research program. The first major release of the toolkit was announced in April-May 2017.

Between 2013 and 2019, development was supported by the NLM intramural research program with collaborators at The University of Iowa and Monash University.

Since 2019, SimpleITK development is supported by the Office of Cyber Infrastructure and Computational Biology at the National Institute of Allergy and Infectious Diseases.

The toolkit release history is available on GitHub.

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by
the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.
2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

   (a) You must give any other recipients of the Work or Derivative Works a copy of this License; and

   (b) You must cause any modified files to carry prominent notices stating that You changed the files; and

   (c) You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

   (d) If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and
do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this
License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

APPENDIX: How to apply the Apache License to your work.

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets "["] replaced with your own identifying information. (Don't include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same "printed page" as the copyright notice for easier identification within third-party archives.

Copyright [yyyy] [name of copyright owner]

See the License for the specific language governing permissions and limitations under the License.
Welcome to SimpleITK!

SimpleITK provides a simplified interface to ITK in a variety of languages. A user can either download pre-built binaries, if they are available for the desired platform and language, or SimpleITK can be built from the source code.

In the following sections we describe how to install SimpleITK and auxiliary software tools.

After installing SimpleITK, we recommend going over the latest tutorial and skimming the Doxygen pages for more information.

2.1 Downloading the binaries

One of the great advantages of SimpleITK is that (typically) the user does not have to build it — he or she can simply download the binaries and get started right away!

Currently, Python binaries are available on Microsoft Windows, GNU Linux and Mac OS X. C# and Java binaries are available for Windows. R binaries are not available but a convenient devtools based installer for Linux and Mac is.

2.1.1 Python binary files

There are currently two Python binary package choices: Python Wheels, and Anaconda packages for the Anaconda Python distribution. We recommend the use of a virtual environment for installation of SimpleITK.

Wheels for Generic Python Distribution

From the command line use the pip program to install a binary wheel:

```
> pip install SimpleITK
```

This installation requires a recent version of pip (>=9.0), to properly detect compatibility with the PEP 427 tags in the wheel filenames. Pip can be updated using `pip install -U pip`. Also the Python environment must be compatible with one of the pre-compiled binary wheels.

Alternatively, the wheels can be manually downloaded from GitHub releases or PyPI, and then installed with pip.
Conda-based distributions (Anaconda, Miniconda)

From the command line prompt, execute:

```
conda install -c conda-forge simpleitk
```

This will install the latest version of SimpleITK that is compatible with the package versions already installed in your environment. To install the latest version of SimpleITK and update all version dependencies, execute:

```
conda install --update-deps -c conda-forge simpleitk
```

Finally, to install a specific version, for example 2.2.1, execute:

```
conda install -c conda-forge simpleitk=2.2.1
```

2.1.2 C# binary files

Binaries for select C# platforms can be found on SimpleITK’s GitHub releases under the appropriate version. Installing the library should only involve importing the unzipped files into the C# environment. The files have the following naming convention:

SimpleITK-version-CSharp-buildplatform-targetplatform.zip

e.g.

SimpleITK-1.2.4-CSharp-win64-x64.zip

Details about how to set up a C# Visual Studio project with SimpleITK can be found in the setup SimpleITK with CSharp page.

2.1.3 Java binary files

Binaries for select Java platforms can be found on SimpleITK’s GitHub releases page under the appropriate version. Installation instructions are available at setup SimpleITK with Java.

2.1.4 R binary files

R binaries are currently only available for Linux and Mac.

SimpleITK/R is installed using a devtools based installer (GitHub Repository). Strictly speaking, this is not a binary distribution, but it is a convenient way of automatically compiling and installing on a system.

This installation requires R devtools, CMake, git, and a compiler in the path.

```
devtools::install_github("SimpleITK/SimpleITKRIInstaller")
```
2.1.5 Latest binaries

If the latest SimpleITK bug fixes and features are required then pre-release binaries are available. The pre-release binaries are built from the actively developed master branch. The SimpleITK packages are available on Github releases under the “latest” tag. The packages include Python, CSharp and Java. To upgrade to the latest pre-release Python binary package run:

```bash
pip install --upgrade --pre SimpleITK --find-links https://github.com/SimpleITK/SimpleITK/releases/tag/latest
```

2.2 Recommended Software

2.2.1 Fiji (Fiji is Just ImageJ)

SimpleITK has a built in function, `itk::simple::Show()`, which can be used for viewing images in an interactive session. By default this Show function searches for an installed Fiji to display images. If Fiji is not found, then it searches for ImageJ. Fiji/ImageJ were chosen because they can handle all the image types that SimpleITK supports, including 3D vector images with n components per pixel.

The Show function searches for Fiji/ImageJ in a number of standard locations. The exact locations depend on the system type (Linux, Mac or Windows). Enabling the “debugOn” option to “Show”, allows the user to see where SimpleITK is searching for Fiji (or other viewing application) and the actual command used to launch the viewing application.

Show is a functional interface to the `ImageViewer` class. Other viewing applications can be configured using an `ImageViewer` object, see the following section of the `Frequently Asked Questions`:

   ```
   Can I use another image file viewer beside Fiji?
   ```

2.2.2 IPython and Jupyter

For python users, IPython with Jupyter is a terrific environment to perform interactive computing for image processing. The addition of the `numpy` and `scipy` packages creates a powerful interactive development environment.

We have instructional SimpleITK Jupyter Notebooks which can help a user get started.
The two basic elements which are at the heart of SimpleITK are images and spatial transformations. These follow the same conventions as the ITK components which they represent. The fundamental underlying concepts are described below.

### 3.1 Images

The fundamental tenet of an image in ITK and consequentially in SimpleITK is that an image is defined by a set of points on a grid occupying a **physical region in space**. This significantly differs from many other image analysis libraries that treat an image as an array which has two implications: (1) pixel/voxel spacing is assumed to be isotropic and (2) there is no notion of an image’s location in physical space.

SimpleITK images are multi-dimensional (the default configuration includes images from 2D up to 5D) and can be a scalar, labelmap (scalar with run length encoding), complex value or have an arbitrary number of scalar channels (also known as a vector image). The region in physical space which an image occupies is defined by the image’s:

1. **Origin** (vector like type) - location in the world coordinate system of the voxel with all zero indexes.
2. **Spacing** (vector like type) - distance between pixels along each of the dimensions.
3. **Size** (vector like type) - number of pixels in each dimension.
4. **Direction cosine matrix** (vector like type representing matrix in row major order) - direction of each of the axes corresponding to the matrix columns.

The meaning of each of these meta-data elements is visually illustrated in [this figure](#).

Fig. 1: An image in SimpleITK occupies a region in physical space which is defined by its meta-data (origin, size, spacing, and direction cosine matrix). Note that the image’s physical extent starts half a voxel before the origin and ends half a voxel beyond the last voxel.

In SimpleITK, when we construct an image we specify its dimensionality, size and pixel type, all other components are set to **reasonable default values**:

1. origin - all zeros.
2. spacing - all ones.
3. direction - identity.
4. intensities in all channels - all zero.

In the following Python code snippet we illustrate how to create a 2D image with five float valued channels per pixel, origin set to (3, 14) and a spacing of (0.5, 2). Note that the metric units associated with the location of the image origin in the world coordinate system and the spacing between pixels are unknown (km, m, cm, mm,…). It is up to you the developer to be consistent. More about that below.
The tenet that images occupy a spatial location in the physical world has to do with the original application domain of ITK and SimpleITK, medical imaging. In that domain images represent anatomical structures with metric sizes and spatial locations. Additionally, the spacing between voxels is often non-isotropic (most commonly the spacing along the inferior-superior/foot-to-head direction is larger). Viewers that treat images as an array will display a distorted image as shown in this figure.

Fig. 2: The same image displayed with a viewer that is not aware of spatial meta-data (left image) and one that is aware (right image). The image’s pixel spacing is (0.97656, 2.0)mm.

As an image is also defined by its spatial location, two images with the same pixel data and spacing may not be considered equivalent. Think of two CT scans of the same patient acquired at different sites. This figure illustrates the notion of spatial location in the physical world, the two images are considered different even though the intensity values and pixel spacing are the same.

Fig. 3: Two images with exactly the same pixel data, positioned in the world coordinate system. In SimpleITK these are not considered the same image, because they occupy different spatial locations. The image on the left has its origin at (-136.3, -20.5) with a direction cosine matrix, in row major order, of (0.7, -0.7, 0.7, 0.7), \[
\begin{pmatrix}
0.7 & -0.7 \\
0.7 & 0.7 
\end{pmatrix}
\]. The image on the right’s origin is (16.9, 21.4) with a direction cosine matrix of (1,0,0,1), \[
\begin{pmatrix}
1 & 0 \\
0 & 1 
\end{pmatrix}
\].

As SimpleITK images occupy a physical region in space, the quantities defining this region have metric units (cm, mm, etc.). In general SimpleITK assume units are in millimeters (historical reasons, due to DICOM standard). In practice SimpleITK is not aware of the specific units associated with each image, it just assumes that they are consistent. Thus, it is up to you the developer to ensure that all of the images you read and created are using the same units. Mixing units and using wrong units has not ended well in the past.

Finally, having convinced you to think of images as objects occupying a physical region in space, we need to answer two questions:

1. How do you access the pixel values in an image?
   a. In dynamically typed languages such as Python and R use a type agnostic function:
   ```python
   image.GetPixel((0,0))
   ```
   b. In statically typed languages such as C# and C++ use type specific functions:
   ```cpp
   image.GetPixelAsUInt8( {0, 0} )
   ```

   SimpleITK functions use a zero based indexing scheme. The toolkit also includes syntactic sugar that allows one to use the bracket operator in combination with the native zero/one based indexing scheme (e.g. a one based indexing in R vs. the zero based indexing in Python).

2. How do you determine the physical location of a pixel:
   ```python
   image.TransformIndexToPhysicalPoint((0,0))
   ```

   This computation can also be done manually using the meta-data defining the image’s spatial location, but we highly recommend that you do not do so as it is error prone.
3.1.1 Channels

As stated above, a SimpleITK image can have an arbitrary number of channels with the content of the channels being a scalar or complex value. This is determined when an image is created.

In the medical domain, many image types have a single scalar channel (e.g. CT, US). Another common image type is a three channel image where each channel has scalar values in [0,255], often people refer to such an image as an RGB image. This terminology implies that the three channels should be interpreted using the RGB color space. In some cases you can have the same image type, but the channel values represent another color space, such as HSV (it decouples the color and intensity information and is a bit more invariant to illumination changes). SimpleITK has no concept of color space, thus in both cases it will simply view a pixel value as a 3-tuple.

Word of caution: In some cases looks may be deceiving. Gray scale images are not always stored as a single channel image. In some cases an image that looks like a gray scale image is actually a three channel image with the intensity values repeated in each of the channels. Even worse, some gray scale images can be four channel images with the channels representing RGBA and the alpha channel set to all 255. This can result in a significant waste of memory and computation time. Always become familiar with your data.

3.1.2 Additional Resources

1. The API for the SimpleITK Image class in Doxygen format.
2. To really understand the structure of SimpleITK images and how to work with them, we recommend some hands-on interaction using the SimpleITK Jupyter notebooks (Python and R only).

3.2 Transforms

SimpleITK supports two types of spatial transforms, ones with a global (unbounded) spatial domain and ones with a bounded spatial domain. Points in SimpleITK are mapped by the transform using the TransformPoint method.

All global domain transforms are of the form:

$$ T(x) = A(x - c) + t + c $$

The nomenclature used in the documentation refers to the components of the transformations as follows:

- Matrix - the matrix $A$.
- Center - the point $c$.
- Translation - the vector $t$.
- Offset - the expression $t + c - Ac$.

A variety of global 2D and 3D transformations are available (translation, rotation, rigid, similarity, affine...). Some of these transformations are available with various parameterizations which are useful for registration purposes.

The second type of spatial transformation, bounded domain transformations, are defined to be identity outside their domain. These include the B-spline deformable transformation, often referred to as Free-Form Deformation, and the displacement field transformation.

The B-spline transform uses a grid of control points to represent a spline based transformation. To specify the transformation the user defines the number of control points and the spatial region which they overlap. The spline order can also be set, though the default of cubic is appropriate in most cases. The displacement field transformation uses a dense set of vectors representing displacement in a bounded spatial domain. It has no implicit constraints on transformation continuity or smoothness.
Finally, SimpleITK supports a **composite transformation** with either a bounded or global domain. This transformation represents multiple transformations applied one after the other $T_0(T_1(T_2(...T_n(p)...)))$. The semantics are stack based, that is, first in last applied:

```python
composite_transform = CompositeTransform([T0, T1])
composite_transform.AddTransform(T2)
```

In the context of registration, if you use a composite transform as the transformation that is optimized, only the parameters of the last transformation $T_n$ will be optimized over.

### 3.2.1 Additional Resources

1. The API for the SimpleITK transformation classes is available in Doxygen format:
   - 2D or 3D translation.
   - VersorTransform.
   - Euler2DTransform and Euler3DTransform.
   - Similarity2DTransform and Similarity3DTransform.
   - 2D or 3D ScaleTransform.
   - ScaleVersor3DTransform.
   - ScaleSkewVersor3DTransform.
   - ComposeScaleSkewVersor3DTransform.
   - 2D or 3D AffineTransform.
   - 2D or 3D BSplineTransform.
   - 2D or 3D DisplacementFieldTransform.
   - CompositeTransform.
   - Transform.

2. To really understand the structure of SimpleITK transforms and how to work with them, we recommend some hands-on interaction using the SimpleITK Jupyter notebooks (Python and R only).

### 3.3 Resampling

Resampling, as the verb implies, is the action of sampling an image, which itself is a sampling of an original continuous signal.

Generally speaking, resampling in SimpleITK involves four components:

1. **Image** - the image we resample, given in coordinate system $m$.
2. **Resampling grid** - a regular grid of points given in coordinate system $f$ which will be mapped to coordinate system $m$.
3. **Transformation $T_f^m$** - maps points from coordinate system $f$ to coordinate system $m$, $m^p = T_f^m(f^p)$.
4. **Interpolator** - method for obtaining the intensity values at arbitrary points in coordinate system $m$ from the values of the points defined by the Image.
While SimpleITK provides a large number of interpolation methods, the two most commonly used are sitkLinear and sitkNearestNeighbor. The former is used for most interpolation tasks and is a compromise between accuracy and computational efficiency. The later is used to interpolate labeled images representing a segmentation. It is the only interpolation approach which will not introduce new labels into the result.

The SimpleITK interface includes three variants for specifying the resampling grid:

1. Use the same grid as defined by the resampled image.
2. Provide a second, reference, image which defines the grid.
3. Specify the grid using: size, origin, spacing, and direction cosine matrix.

Points that are mapped outside of the resampled image’s spatial extent in physical space are set to a constant pixel value which you provide (default is zero).

### 3.3.1 Common Errors

It is not uncommon to end up with an empty (all black) image after resampling. This is due to:

1. Using wrong settings for the resampling grid (not too common, but does happen).
2. Using the inverse of the transformation $T_{m}^{n}$. This is a relatively common error, which is readily addressed by invoking the transformation’s $\text{GetInverse}$ method.

### 3.3.2 Additional Resources

1. The API for the SimpleITK ResampleImageFilter class in Doxygen format. The procedural interface for this class supports the three variations for specifying the resampling grid described above.
2. To really understand the structure of SimpleITK images and how to work with them we recommend some hands-on interaction using the SimpleITK Jupyter notebooks (Python and R only).
CHAPTER FOUR

REGISTRATION OVERVIEW

The goal of registration is to estimate the transformation which maps points from one image to the corresponding points in another image. The transformation estimated via registration is said to map points from the fixed image coordinate system to the moving image coordinate system.

SimpleITK provides a configurable multi-resolution registration framework, implemented in the ImageRegistrationMethod class. In addition, a number of variations of the Demons registration algorithm are implemented independently from this class as they do not fit into the framework.

4.1 Actual Code

Code illustrating various aspects of the registration framework can be found in the set of examples which are part of the SimpleITK distribution and in the SimpleITK Jupyter notebook repository.

4.2 Initialization and Center of Rotation

The task of registration is formulated using non-linear optimization which requires an initial estimate. The two most common initialization approaches are (1) Use the identity transform (a.k.a. forgot to initialize). (2) Align the physical centers of the two images (see CenteredTransformInitializerFilter). If after initialization there is no overlap between the images, registration will fail. The closer the initialization transformation is to the actual transformation, the higher the probability of convergence to the correct solution.

If your registration involves the use of a global domain transform (described here), you should also set an appropriate center of rotation. In many cases you want the center of rotation to be the physical center of the fixed image (the CenteredTransformCenteredTransformInitializerFilter ensures this). This is of significant importance for registration convergence due to the non-linear nature of rotation. When the center of rotation is far from our physical region of interest (ROI), a small rotational angle results in a large displacement. Think of moving the pivot/fulcrum point of a lever. For the same rotation angle, the farther you are from the fulcrum the larger the displacement. For numerical stability we do not want our computations to be sensitive to very small variations in the rotation angle, thus the ideal center of rotation is the point which minimizes the distance to the farthest point in our ROI:

\[
p_{\text{center}} = \arg \min_{p_{\text{rotation}}} \text{dist}(p_{\text{rotation}}, \{p_{\text{roi}}\})
\]

Without additional knowledge we can only assume that the ROI is the whole fixed image. If your ROI is only in a subregion of the image, a more appropriate point would be the center of the oriented bounding box of that ROI.
4.3 ImageRegistrationMethod

To create a specific registration instance using the ImageRegistrationMethod you need to select several components which together define the registration instance:

1. Transformation.
2. Similarity metric.
3. Optimizer.
4. Interpolator.

4.3.1 Transform

The type of transformation defines the mapping between the two images. SimpleITK supports a variety of global and local transformations. The available transformations include:

- TranslationTransform.
- VersorTransform.
- VersorRigid3DTransform.
- Euler2DTransform.
- Euler3DTransform.
- Similarity2DTransform.
- Similarity3DTransform.
- ScaleTransform.
- ScaleVersor3DTransform.
- ScaleSkewVersor3DTransform.
- ComposeScaleSkewVersor3DTransform.
- AffineTransform.
- BSplineTransform.
- DisplacementFieldTransform.
- Composite Transform.

The parameters modified by the registration framework are those returned by the transforms GetParameters() method. This requires special attention when using a composite transform, as the specific parameters vary based on the content of your composite transformation.
4.3.2 Similarity Metric

The similarity metric reflects the relationship between the intensities of the images (identity, affine, stochastic…). The available metrics include:

- MeanSquares.
- Demons.
- Correlation.
- ANTSNeighborhoodCorrelation.
- JointHistogramMutualInformation.
- MattesMutualInformation.

In the ITKv4 and consequentially in SimpleITK all similarity metrics are minimized. For metrics whose optimum corresponds to a maximum, such as mutual information, the metric value is negated internally. The selection of a similarity metric is done using the ImageRegistrationMethod’s SetMetricAsX() methods.

4.3.3 Optimizer

The optimizer is selected using the SetOptimizerAsX() methods. When selecting the optimizer you will also need to configure it (e.g. set the number of iterations). The available optimizers include:

- Gradient free
  - Exhaustive.
  - Nelder-Mead downhill simplex (Amoeba).
  - Powell.
  - 1+1 evolutionary optimizer.
- Gradient based:
  - Gradient Descent.
  - Gradient Descent Line Search.
  - Regular Step Gradient Descent.
  - Conjugate Gradient Line Search.
  - L-BFGS-B, Limited memory Broyden, Fletcher, Goldfarb, Shannon, Bound Constrained (supports the use of simple constraints).

4.3.4 Interpolator

SimpleITK has a large number of interpolators. In most cases linear interpolation, the default setting, is sufficient. Unlike the similarity metric and optimizer, the interpolator is set using the SetInterpolator method which receives a parameter indicating the interpolator type.
4.3.5 Features of Interest

Transforms and image spaces

While the goal of registration, as defined above, refers to a single transformation and two images, the ITKv4 registration and the SimpleITK ImageRegistrationMethod provide additional flexibility in registration configuration.

From a coordinate system standpoint ITKv4 introduced the virtual image domain, making registration a symmetric process so that both images are treated similarly. As a consequence the ImageRegistrationMethod has methods for setting three transformations:

1. SetInitialTransform $T_o$ - composed with the moving initial transform, maps points from the virtual image domain to the moving image domain, modified during optimization.
2. SetFixedInitialTransform $T_f$ - maps points from the virtual image domain to the fixed image domain, never modified.
3. SetMovingInitialTransform $T_m$ - maps points from the virtual image domain to the moving image domain, never modified.

The transformation that maps points from the fixed to moving image domains is thus:

$$ p_{moving} = T_o(T_m(T_f^{-1}(p_{fixed}))) $$

Multi Resolution Framework

The ImageRegistrationMethod supports multi-resolution, pyramid, registration via two methods SetShrinkFactorsPerLevel and SetSmoothingSigmasPerLevel. The former receives the shrink factors to apply when moving from one level of the pyramid to the next and the later receives the sigmas to use for smoothing when moving from level to level. Sigmas can be specified either in voxel units or physical units (default) using SetSmoothingSigmasAreSpecifiedInPhysicalUnits.

Sampling

For many registration tasks one can use a fraction of the image voxels to estimate the similarity measure. Aggressive sampling can significantly reduce the registration runtime. The ImageRegistration method allows you to specify how/if to sample the voxels, SetMetricSamplingStrategy, and if using a sampling, what percentage, SetMetricSamplingPercentage.

The registration framework supports three sampling strategies:

1. NONE - use all voxels, sampled points are the voxel centers.
2. REGULAR - sample every n-th voxel while traversing the image in scan-line order, then within each voxel randomly perturb from center.
3. RANDOM - sample image voxels with replacement using a uniform distribution, then within each voxel randomly perturb from center.

When using the REGULAR or RANDOM sampling strategies, running the same registration code multiple times will yield different results. To remove the randomness, set the pseudo-random number generator’s seed in the SetMetricSamplingPercentage method to a constant. The default seed value is wall clock time.

Note that using the RANDOM sampling strategy with a 100% sampling rate is not equivalent to using the sampling strategy of NONE. Given an image with N voxels, the former randomly selects N voxels with repetition and perturbs the points within each voxel, the latter uses the centers of all N voxels. Thus, for repeated random sampling with 100% rate, different samples are produced and likely none of them is of the centers of all N voxels.
Combining a mask with sampling is done using a rejection approach. First a sample is generated and then it is accepted or rejected if it is inside or outside the mask. This may cause problems when the mask region occupies a very small region in the original image. Because the sampling only discards data, the sample rate may be reduced from the requested one. For some similarity metrics (e.g., mutual information) this can result in an insufficient number of samples for metric value computation, leading to registration failure. Other metrics are more robust to small sample sizes (e.g., mean squares), but they all suffer from it. In such cases it is better to use a cropped version of the image for registration, possibly the mask’s bounding box, instead of the original image with a mask.

### Scaling in Parameter Space

The ITKv4 framework introduced automated methods for estimating scaling factors for non-commensurate parameter units. These change the step size per parameter so that the effect of a unit of change has similar effects in physical space (think rotation of 1 radian and translation of 1 millimeter). The relevant methods are `SetOptimizerScalesFromPhysicalShift`, `SetOptimizerScalesFromIndexShift` and `SetOptimizerScalesFromJacobian`. In many cases this scaling is what determines if the the optimization converges to the correct optimum.

### Observing Registration Progress

The `ImageRegistrationMethod` enables you to observe the registration process as it progresses. This is done using the Command-Observer pattern, associating callbacks with specific events. To associate a callback with a specific event use the `AddCommand` method.

### Reproducibility

Generally speaking, repeated registrations of the same datasets will yield slightly different results. This is associated with the registration framework’s similarity metric computation implementation which utilizes both randomization and multi-threading.

The primary source of variability is the use of randomization. To eliminate randomization variability, set the seed parameter for the `SetMetricSamplingPercentage` to a fixed value (e.g., 42).

The secondary, and much more minor, source of variability has to do with the multithreading implementation, different order of operations in each registration run. To eliminate multithreading variability, set the number of threads to one via the `SetGlobalDefaultNumberOfThreads` method. From a practical standpoint, in the tradeoff between full reproducibility and computational efficiency with minor variability in results, computational efficiency is most often more important.
CHAPTER
FIVE

COMMON CONVENTIONS

This document contains common conventions that SimpleITK filters, and objects follow. It is intended to describe the interfaces that users should use and developers should implement. If a method or class does not specify different behavior or default values then those described here, it should be assumed that it follows the following conventions.

5.1 Naming

The object oriented interface of process objects are named based on the specific operation they perform on their input image(s) with a suffix of `ImageFilter`, the ITK convention. For example, `AbsImageFilter`, `BinaryMinMaxCurvatureFlowImageFilter` etc. For almost all process objects there is also a procedural interface. This interface provides one or more functions which allow setting parameter values and invoking the operation in one call. This results in concise code and is useful if the filter is only applied once. These functions use the same naming as the object oriented interface only without the suffix. That is, the corresponding procedural methods to the object oriented interface examples above are `Abs` and `BinaryMinMaxCurvatureFlow`.

Note that the complete/detailed documentation appears in the doxygen of the object oriented interface.

5.2 Dimensional Vectors

Dimensional Vectors must contain at least the number of elements as the dimensions of the image, elements beyond the image’s dimension will be truncated.

The SimpleITK image class can contain 2 or 3 dimensional images. In ITK proper, certain types such as indexes, points, and sizes are templated over the image dimensions. In SimpleITK we utilize the variable length `std::vector` for these types, so that non-templated calls can wrap ITK’s templated image class. These types are called Dimensional Vectors. If a dimensional vector’s length is less that the dimension of the image, an exception will be generated when converted to the ITK type. If there are extra elements in the dimensional vector these values will be ignored.

5.3 Image Access

Image access is in x,y,z order, `GetPixel(x,y,z)` or `image[x,y,z]`, with zero based indexing.
5.4 Mask Image Types and Default Values

The default mask image type is a scalar image of `sitkUInt8` or `uint8_t` pixels. The default values are 0 and 1, with 1s representing the mask.

These defaults are for filter which create masks such as thresholding, and certain other segmentation filters. Additionally, these are the defaults for the binary morphology filters, so that they can easily be applied after segmentation. This choice makes many mask manipulations easier. For example, “masking” an image (scalar or vector) is simply a matter of multiplying by a mask an image. Additionally, the set of \{0, 1\} pixels is closed under the logical Boolean operators.

5.5 Order of Procedural Parameters

The order of the procedural parameters should be with the most frequently modified parameters at the beginning of the parameter list. While the last parameter, may be ones that the user does not need to set or are infrequently used.

5.6 Matrices as Parameters

Matrices are represented as a single dimensional vector with the entries in row major order. The vector \[1, 2, 3, 4, 5, 6\] represents the matrix

\[
\begin{bmatrix}
1 & 2 & 3 \\
4 & 5 & 6
\end{bmatrix}
\]

5.7 Image Regions as Index and Size

The `itk::ImageRegion` is a frequently used class in ITK to define a sub-image area. It is defined by `itk::Index` and `itk::Size` of signed and unsigned integer types respectfully. In SimpleITK, the index and size elements are usually separated into two arguments with separate Set and Get methods.

When specified as a single argument value, it is a 1 dimensional array with the index values followed by the size values i.e. \[idx_x, idx_y, idx_z, size_x, size_y, size_z\].

5.8 Images As Parameters

The dimensionality (2D or 3D) and pixel type (`sitkUInt8`, `sitkFloat64`...) of images is required to be the same for most methods that receive multiple images as input.

The `ImageRegistrationMethod` only supports images with `sitkFloat32` and `sitkFloat64` pixel types.

Casting an image’s pixel type into another is done with the SimpleITK `Cast()` function.
6.1 Images

There are numerous file formats supported by SimpleITK’s image readers and writers. Support for a particular format is handled by a specific ITK ImageIO class. By default, the ImageIO is automatically determined for a particular file based on the file name suffix and/or the contents of the file’s header. Advanced SimpleITK installations can configure or extend which file formats are supported by SimpleITK. A list of registered ImageIO’s can be found using the GetRegisteredImageIOs() method, but is posted here:

- BMPImageIO  (*.bmp, *.BMP)
- BioRadImageIO  (*.PIC, *.pic)
- Bruker2dseqImageIO
- GDCMImageIO
- GE4ImageIO
- GE5ImageIO
- GiplImageIO  (*.gipl, *.gipl.gz)
- HDF5ImageIO
- JPEGImageIO  (*.jpg, *.JPG, *.jpeg, *.JPEG)
- MINCImageIO  (*.mnc, *.MNC)
- MRCImageIO  (*.mrc, *.rec)
- MetaImageIO  (*.mha, *.mhd)
- NrrdImageIO  (*.nrrd, *.nhdr)
- PNGImageIO  (*.png, *.PNG)
- StimulateImageIO
- TIFFImageIO  (*.tif, *.TIF, *.tiff, *.TIFF)
- VTKImageIO  (*.vtk)

A read and write example using SimpleITK’s ImageFileReader and ImageFileWriter classes:

C#
SimpleITK Documentation, Release 2.0rc2

```plaintext
ImageFileReader reader = new ImageFileReader();
reader.SetImageIO("PNGImageIO");
reader.SetFileName(inputImageFileName);
Image image = reader.Execute();

ImageFileWriter writer = new ImageFileWriter();
writer.SetFileName(outputImageFileName);
writer.Execute(image);
```

C++

```plaintext
itk::simple::ImageFileReader reader;
reader.SetImageIO("PNGImageIO");
reader.SetFileName(inputImageFileName);

itk::simple::Image image;
image = reader.Execute();

itk::simple::ImageFileWriter writer;
writer.SetFileName(outputImageFileName);
```

Java

```plaintext
ImageFileReader reader = new ImageFileReader();
reader.setImageIO("PNGImageIO");
reader.setFileName(inputImageFileName);
Image image = reader.execute();

ImageFileWriter writer = new ImageFileWriter();
writer.setFileName(outputImageFileName);
```

Lua

```plaintext
require "SimpleITK"
reader = SimpleITK.ImageFileReader()
reader:SetImageIO("PNGImageIO")
reader:SetFileName(inputImageFileName)
image = reader:Execute();

writer = SimpleITK.ImageFileWriter()
writer:setFileName(outputImageFileName)
```

Python

```plaintext
import SimpleITK as sitk
reader = sitk.ImageFileReader()
reader.SetImageIO("PNGImageIO")
reader.SetFileName(inputImageFileName)
image = reader.Execute()
```

(continues on next page)
The above example specifies using the PNGImageIO to read the file. If that line is omitted, SimpleITK would determine which IO to use automatically, based on the file name’s suffix and/or the file’s header.

A more compact example using SimpleITK’s procedural interface:

C#
Image image = sitk.ReadImage(inputImageFileName, PixelIDValueEnum.sitkUnknown, "PNGImageIO");
sitk.WriteImage(image, outputImageFileName);

C++

```cpp
itk::simple::Image image;
image = itk::simple::ReadImage(inputImageFileName, itk::simple::sitkUnknown, "PNGImageIO");
```

Java

```java
Image image = SimpleITK.readImage(inputImageFileName, PixelIDValueEnum.sitkUnknown, "PNGImageIO");
SimpleITK.writeImage(image, outputImageFileName);
```

Lua

```lua
require "SimpleITK"
image = SimpleITK.ReadImage(inputImageFileName, SimpleITK.sitkUnknown, "PNGImageIO")
SimpleITK.WriteImage(image, outputImageFileName)
```

Python

```python
import SimpleITK as sitk
image = sitk.ReadImage(inputImageFileName, imageIO="PNGImageIO")
sitk.WriteImage(image, outputImageFileName)
```

R

```r
library(SimpleITK)
image <- ReadImage(inputImageFileName)
WriteImage(image, outputImageFileName)
```

Ruby

```ruby
require 'simpleitk'
image = Simpleitk::read_image(inputImageFileName, Simpleitk::SitkUnknown, "PNGImageIO")
Simpleitk::write_image(image, outputImageFileName)
```

Tcl

```tcl
global sitkUnknown
set image [ ReadImage $inputImageFileName $sitkUnknown "PNGImageIO" ]
WriteImage $image $outputImageFileName
$image -delete
```

Similarly, if the imageIO parameter is omitted, SimpleITK will determine which IO to use automatically.
Finally, one can also specify the desired pixel type for the returned image, regardless of the underlying pixel type. This is done via the SetOutputPixelType of the ImageFileReader or setting the ReadImage's outputPixelType parameter.

When reading a scalar image and specifying a different scalar type from the underlying one, the returned image's pixel type will be a simple casting of the actual type. This casting can result in loss of data when performing a narrowing conversion. For example, if the underlying pixel type is sitk.sitkFloat32 and the specified pixel type is sitk.sitkUInt8. Explicitly specifying a pixel type is commonly done in conjunction with the SimpleITK registration framework. This framework only accepts images with float pixel types. Therefore, it is common to read the images and specify their pixel type as sitk.sitkFloat32 or sitk.sitkFloat64.

When reading a vector image and specifying the pixel type as a scalar, the returned pixel values are computed based on the number of channels in the original image. This conversion makes several assumptions, three channels mean an RGB image, four channels an RGBA image. These assumptions are useful, but may not be what you need if the original image was not in these color-spaces (e.g. HSV).

For those looking for further details, the ITK class which deals with these conversions is ConvertPixelBuffer.

### 6.2 Transformations

In SimpleITK, transformation files can be written in several different formats. Just as there are numerous IOs for images, there are several for transforms, including TxtTransformIO, MINCTransformIO, HDF5TransformIO, and MatlabTransformIO (although this list can be extended as well). These support a variety of file formats, including .txt, .tfm, .xfm, .hdf and .mat.

Because of the size of displacement fields, writing them may require more careful attention. To save a displacement field we recommend using one of the binary transformation file formats (e.g. .hdf, .mat). Saving it in a text based format results in significantly larger files and longer IO runtimes. Another option is to save the displacement field found in a DisplacementFieldTransform object as an image (.nrrd, .nhdr, .mha, .mhd, .nii, .nii.gz).

Here is a simple example of creating a transformation, writing it to a file, reading it back, and then comparing the results.

**C#**

```csharp
Euler2DTransform basic_transform = new Euler2DTransform();
VectorDouble trans = new VectorDouble( new double[] {2.0, 3.0} );
basic_transform.SetTranslation(trans);
sitk.WriteTransform(basic_transform, "euler2D.tfm");

Transform read_result = sitk.ReadTransform("euler2D.tfm");

Debug.Assert( basic_transform.GetName() != read_result.GetName() );
```

**C++**

```cpp
itk::simple::Euler2DTransform basic_transform;
basic_transform.SetTranslation(std::vector<double> {2.0, 3.0});

itk::simple::WriteTransform(basic_transform, "euler2D.tfm");

itk::simple::Transform read_result = itk::simple::ReadTransform("euler2D.tfm");
```

**Java**

```java
6.2. Transformations 31
```
Euler2DTransform basic_transform = new Euler2DTransform();
double[] t = {2.0, 3.0};
VectorDouble trans = new VectorDouble(t);
basic_transform.setTranslation(trans);

SimpleITK.writeTransform(basic_transform, "euler2D.tfm");
Transform read_result = SimpleITK.readTransform("euler2D.tfm");

assert basic_transform.getClass() != read_result.getClass();
basic_transform = Simpleitk::Euler2DTransform.new
trans = Simpleitk::VectorDouble.new
trans << 2.0
trans << 3.0
basic_transform.set_translation(trans)

Simpleitk::write_transform(basic_transform, 'euler2D.tfm')
read_result = Simpleitk::read_transform('euler2D.tfm')

raise "This shouldn't happen." unless basic_transform.class != read_result.class

Tcl

Euler2DTransform basic_transform
set trans { 2.0 3.0 }
basic_transform SetTranslation $trans

WriteTransform basic_transform "euler2D.tfm"
set read_result [ ReadTransform "euler2D.tfm" ]

if { [Basic_transform GetName] == [$read_result GetName] } {
    error "This should not happen" 1
}

basic_transform -delete
$read_result -delete

In all languages, except Python, read_result returns an object of the generic sitk.Transform() class and basic_transform creates a sitk.Euler2DTransform() object, but both represent the same transformation. Although this example only uses a single SimpleITK transformation, a .tfm file can hold a composite (set of transformations).
### CHAPTER SEVEN

**SIMPLE ITK FILTERS**

<table>
<thead>
<tr>
<th>Filter Name</th>
<th>Brief Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AbsImageFilter</td>
<td>Computes the absolute value of each pixel.</td>
</tr>
<tr>
<td>AbsoluteValueDifferenceImageFilter</td>
<td>Implements pixel-wise the computation of absolute value difference.</td>
</tr>
<tr>
<td>AcosImageFilter</td>
<td>Computes the inverse cosine of each pixel.</td>
</tr>
<tr>
<td>AddImageFilter</td>
<td>Pixel-wise addition of two images.</td>
</tr>
<tr>
<td>AdditiveGaussianNoiseImageFilter</td>
<td>Alter an image with additive Gaussian white noise.</td>
</tr>
<tr>
<td>AggregateLabelMapFilter</td>
<td>Collapses all labels into the first label.</td>
</tr>
<tr>
<td>AndImageFilter</td>
<td>Implements the AND bitwise operator pixel-wise between two images.</td>
</tr>
<tr>
<td>ApproximateSignedDistanceMapImageFilter</td>
<td>Create a map of the approximate signed distance from the boundaries of a binary image.</td>
</tr>
<tr>
<td>AsinImageFilter</td>
<td>Computes the sine of each pixel.</td>
</tr>
<tr>
<td>Atan2ImageFilter</td>
<td>Computes two argument inverse tangent.</td>
</tr>
<tr>
<td>AtanImageFilter</td>
<td>Computes the one-argument inverse tangent of each pixel.</td>
</tr>
<tr>
<td>BSplineDecompositionImageFilter</td>
<td>Calculates the B-Spline coefficients of an image. Spline order may be from 0 to 5.</td>
</tr>
<tr>
<td>BilateralImageFilter</td>
<td>Blurs an image while preserving edges.</td>
</tr>
<tr>
<td>BinShrinkImageFilter</td>
<td>Reduce the size of an image by an integer factor in each dimension while performing averaging of an input neighborhood.</td>
</tr>
<tr>
<td>BinaryClosingByReconstructionImageFilter</td>
<td>Binary closing by reconstruction of an image.</td>
</tr>
<tr>
<td>BinaryContourImageFilter</td>
<td>Labels the pixels on the border of the objects in a binary image.</td>
</tr>
<tr>
<td>BinaryDilateImageFilter</td>
<td>Fast binary dilation of a single intensity value in the image.</td>
</tr>
<tr>
<td>BinaryErodeImageFilter</td>
<td>Fast binary erosion of a single intensity value in the image.</td>
</tr>
<tr>
<td>BinaryFillholeImageFilter</td>
<td>Remove holes not connected to the boundary of the image.</td>
</tr>
<tr>
<td>BinaryGrindPeakImageFilter</td>
<td>Remove the objects not connected to the boundary of the image.</td>
</tr>
<tr>
<td>BinaryImageToLabelMapFilter</td>
<td>Label the connected components in a binary image and produce a collection of label objects.</td>
</tr>
<tr>
<td>BinaryMagnitudeImageFilter</td>
<td>Computes the square root of the sum of squares of corresponding input pixels.</td>
</tr>
<tr>
<td>BinaryMedianImageFilter</td>
<td>Applies a version of the median filter optimized for binary images.</td>
</tr>
<tr>
<td>BinaryMinMaxCurvatureFlowImageFilter</td>
<td>Denoise a binary image using min/max curvature flow.</td>
</tr>
</tbody>

</tbody>
</table>
Pre-built binaries (see *Downloading the binaries*) are available in many cases so users do not need to build SimpleITK. However, there are several reasons a user might prefer to build SimpleITK from source code:

- The binary files for your programming language of choice are not (yet) distributed
- You want the live on the bleeding edge by using the latest-and-greatest version of SimpleITK
- You want to wrap your own filters using the SimpleITK infrastructure
- You want to contribute to the development of SimpleITK
- To use the SimpleITK’s C++ interface and/or use ITK directly

### 8.1 Prerequisites

To build SimpleITK you need:

- A recent version of **CMake >= 3.16.3** with SSL support for https.
- A supported **compiler**.
- To use the latest developmental version, source code can be downloaded with **git >= 1.65**
  - Git is required if building SimpleITK using **SuperBuild** to automatically download the matching version of ITK, SWIG, etc…
  - Windows users may prefer **msysGit**
- The Python interface requires Python version 3.5 or greater.
- It is recommended to have numpy installed when testing Python bindings.
- The R interface requires R version 3.3 or greater.

### 8.2 System Requirements

Building SimpleITK requires a significant amount of compute power, and we recommend a reasonably powerful, modern computer. We suggest at least 4 gigabytes (GB) of RAM plus an additional 2 GB per thread when building with multiple threads. We also suggest a system with at least 4 cores for multithreaded compilation.

Building a SuperBuild of SimpleITK’s C++ core including all the testing and example code requires approximately 10 GB of disk space. Enabling the wrapping of Python or R can add 2 GB per language, and enabling the wrapping of all the languages SimpleITK supports, can bring the entire build folder to 16 GB.
8.3 Recipes / Formulas / Short cuts

Before you start please make sure you have the required Prerequisites installed.

For some environments we have short cuts, scripts, for automated building of SimpleITK (see their repository for more details):

- For **Python**: The scikit-build based distutils based setup.py frontend can be used to build, install, and package SimpleITK for Python.
- For the **Anaconda Python** distribution: The recipe and instructions for the SimpleITK build are in this GitHub repository.
- For the **R language** (version 3.3 or greater): A devtools installer and instructions are available from this GitHub repository.
- For the **Lua language** with the Luarocks module deployment system, a SimpleITK rockspec is available at the Luarocks repository or from this GitHub repository.

8.4 Source code

If one of the above language specific front-ends are not used then SimpleITK must be built directly.

Before you start please make sure you have the required Prerequisites installed.

All of the instructions assume you are working on the command line.

Words of caution for building on the Windows operating system:

- Windows has issues with long directory paths. We recommend cloning the source code near the root (e.g. C:\src).
- To avoid potential issues do not clone the source into a path which has spaces in the directory name (e.g. C:\Users\SimpleITK Source).

First obtain the SimpleITK source code:

1. Download the latest development version using git

   ```
git clone https://github.com/SimpleITK/SimpleITK.git
   ```

8.5 Building using SuperBuild

After downloading SimpleITK’s source code we **STRONGLY** recommend running cmake on the SuperBuild subdirectory of SimpleITK. Execute the following commands in the parent of the SimpleITK source directory to configure the SuperBuild:

```
mkdir SimpleITK-build
cd SimpleITK-build
cmake ../SimpleITK/SuperBuild
```

The SuperBuild will automatically download and build the matching versions of ITK, SWIG, Lua, and GTest (if testing is enabled) needed to compile SimpleITK.

If you get an error message saying that ITK_DIR is not set then, you did not correctly point cmake to the SuperBuild sub-directory. Please erase your binary directory, and point cmake to the SimpleITK/SuperBuild sub-directory.
The CMake configuration process should automatically find supported languages and enable SimpleITK wrapping for them. To manually enable a language toggle the appropriate WRAP_LANGUAGE cmake variable to ON. Verify and correct the advanced cmake variables for the language specific executable, libraries and include directories. For example if you have multiple Python installations ensure that all related Python variables refer to the same versions.

Then use your make utility or your cmake chosen build utility to build SimpleITK. As the SimpleITK build process may take a while, it is important to use the appropriate flags to enable multi-process compilation i.e. “-j” for make, “/MP” for Visual Studio, or use the CMake Ninja generator.

For building SimpleITK on Windows using the CMake GUI see:

8.5.1 Building SimpleITK on Windows

Path Length Issues on Windows

The Windows API, by default, has a Maximum Path Length Limitation of 260 characters. This limitation can cause problems when building SimpleITK using the Superbuild process.

For this reason we recommend placing SimpleITK’s source and build directories at the top of the file system. For example, place the source code in C:SimpleITK and set the build directory to be C:SimpleITK-build.

Trying to build SimpleITK with too long a path length will result in an error like so:

```
CMake Error at CMakeLists.txt:109 (message):
  -- Configuring incomplete, errors occurred!
See also "C:/Users/dchen/VeryVeryLongPathName/SimpleITK-build/ITK-build/CMakeFiles/
  --CMakeOutput.log".
  ITK source code directory path length is too long (55 > 50). Please move the
  ITK source code directory to a directory with a shorter path.
```

C:\Program Files (x86)\Microsoft Visual Studio\2019\Community\MSBuild\Microsoft\VC\v160\Microsoft.CppCommon.targets(238,5): error MSB8066: C
ustom build for 'C:\Users\dchen\VeryVeryLongPathName\SimpleITK-build\CMakeFiles\
  --49f9d16effa529c310c9be3182f62407\ITK-mkdir.rule;C:\Users\dchen\VeryVeryLongPathName\SimpleITK-build\CMakeFiles\49f9d16effa529c310c9be3182f62407\ITK-

[C:\Users\dchen\VeryVeryLongPathName\SimpleITK-build\ITK.vcxproj]

8.5. Building using SuperBuild
Building SimpleITK with long path names

If SimpleITK must be built with long path names, two things need to be done:

1. Enable Long Paths in Windows 10, Version 1607, and Later
2. Set the ITK_SKIP_PATH_LENGTH_CHECKS cmake variable to ON in the External_ITK.cmake

Enabling Long Paths in Windows

As described in Microsoft’s documentation, Long path names are enabled in Windows by editing the registry with the following PowerShell command:

```
New-ItemProperty -Path "HKLM:\SYSTEM\CurrentControlSet\Control\FileSystem" -Name "LongPathsEnabled" -Value 1 -PropertyType DWORD -Force
```

The LongPathsEnabled property can also be edited using the Registry Editor app.

Setting ITK_SKIP_PATH_LENGTH_CHECKS

Next ITK needs to be configured so that it does NOT check path lengths in the build process. To disable the path length check, we simply need to add the entry ITK_SKIP_PATH_LENGTH_CHECKS to the CMake configuration, and set its value to ON. We can do this in the CMake GUI when we configure our SimpleITK SuperBuild.

After the initial configuration of the build, click on the “Add Entry” button, enter ITK_SKIP_PATH_LENGTH_CHECKS for the name, and click the Value checkbox to turn set the entry to ON.

Now we can build ITK within the SimpleITK SuperBuild with long path names.
This page describes how to build a SimpleITK SuperBuild on Windows. To build SimpleITK we use CMake to generate a Visual Studio project, and Visual Studio to compile the C/C++ code. To obtain the SimpleITK source code see Source code.

CMake GUI on Windows

The Windows version of CMake includes a graphical-user-interface (GUI) version of the program, in addition to the standard command-line CMake. Here is what the CMake GUI looks like:

In the above example, the source directory is C:/SimpleITK/SuperBuild, and the build directory is C:/SimpleITK-build. It is best to place the source and build directories at the root of a volume to minimize path name lengths. Windows has a default max path length of 260 characters, and ITK has long paths which can cause build issues.

See Windows Path Length for more information.
After the user specifies the source and build directories, CMake will ask to select which compiler generator to use. The options are determined by what versions of Visual Studio are installed on the system. The user must specify x64 for the platform version, since the default option (x86) is not supported by SimpleITK.

**Configuring and Generating the Build**
The next steps are the configuration and generation processes. By clicking the **Configure** button, cmake reads the `CMakeLists.txt` file and sets up all the variables in the CMake cache (`CMakeCache.txt`). Then when the **Generate** button is clicked, CMake creates the Visual Studio build system.

The left image of the above figure is the result of the configure process, and on the right is the result of the generation process.

Note for the **CMAKE_CXX_FLAGS** and **CMAKE_C_FLAGS** variables, we have appended the ‘/MP’ flag, enabling multiple processor when building with Visual Studio. This flag is *not* enabled by default.

### Building SimpleITK in Visual Studio

After CMake has completed the generation process, the user can actually build SimpleITK with Visual Studio. The user should select a build type in Visual Studio. We recommend choosing **Release** or **MinSizeRel** (release with minimum size), since the performance of SimpleITK with the Debug option is several orders of magnitude slower. Also the user must select the **x64** build platform, since the default platform (x86) is not supported by SimpleITK. Many man hours and cpu cycles have been wasted building SimpleITK without setting the proper platform.
To begin the build process in Visual Studio, select **Build ALL_BUILD** in the **Build** menu.

Once the build has completed with no failures, the build can be verified with the following commands entered in a PowerShell:

```
    cd C:\SimpleITK-build\SimpleITK-build
    ctest -R Release
```

Running ctest executes all the built in test code for SimpleITK, more than 500 tests for the core C++ code, and approximately another 500 tests per wrapped language (e.g. Python, CSharp, R, Lua, etc.).

These commands assume that the SimpleITK build directory is `C:\SimpleITK-build` and that the build is a Release build.

### 8.6 Building Manually

By not using the superbuild, you must manually specify all dependencies used during the building of SimpleITK instead of using the known working versions provided by the superbuild as external projects. This may be useful if you are providing a system package of SimpleITK or tightly integrating it into another build system. The versions of external projects used and tested by SimpleITK can be found by examining the External CMake files in the Superbuild sub-directory.
8.6.1 Additional Prerequisites

The following are dependencies you will need when not using the SuperBuild:

1. Setup the prerequisites as described above (i.e. CMake and supported compiler)
2. Insight Toolkit (ITK) the version specified in the External_ITK.cmake file is the version of ITK used for the binary release. This can be seen as the minimum version of ITK to be used with SimpleITK, as future ITK versions are generally backwards compatible.
3. Lua 5.3.5
4. SWIG \( \geq 4.0 \)
5. GTest or Google Test \( \geq 1.10 \) is needed if testing is enabled.

8.6.2 Configuration and Building

After the source code is obtained, SimpleITK can be configured on Unix-like systems like so:

```bash
mkdir SimpleITK-build
cd SimpleITK-build
cmake ../SimpleITK
```

If all the dependencies are installed in standard places, then the CMake configuration should detect them properly. Otherwise, if there are configuration errors, the proper CMake variable should be set. CMake variables can be either set with a CMake interactive GUI such as `ccmake` or `cmake-qt`, as arguments on the command line by using the following format: `-D<var>=<value>`, or by editing the `CMakeCache.txt` file.

After proper configuration, SimpleITK can be built:

```bash
make -j$(nproc)
```

8.6.3 Advanced Build Options

SimpleITK is aware of the modularity of ITK and automatically enables and disables filters based on which modules are available from the ITK build which SimpleITK is compiled against. This makes it possible to customize SimpleITK to be a small library or to wrap additional ITK remote modules simply by configuring ITK with the desired modules enabled.

For example, the CoherenceEnhancingDiffusionImageFilter is an optional filter in SimpleITK as it’s part of the ITK remote module AnisotropicDiffusionLBR. This remote module is not enabled by default when building ITK and SimpleITK. To enable it when using SimpleITK’s Superbuild add `-DModule_AnisotropicDiffusionLBR:BOOL=ON` to the command line or in the CMake GUI press the “Add Entry” button to define the variable as above.

SimpleITK has a very flexible and robust build system utilizing CMake. It enables packagers to build SimpleITK in a variety of ways to suit their requirements and minimize recompilation of SimpleITK so that it can be wrapped for many different languages. Each of the language wrapping sub-directories e.g. “Wrapping/Python” can be configured and built as an independent project which is dependent on SimpleITK as an installed package of its libraries and header files.
8.6.4 Testing

After compilation the prudent thing to do is to test SimpleITK to ensure that the build is stable and suitable for installation and use. To enable testing the cmake BUILD_TESTING variable must be enabled during the build process. Then the following commands execute the SimpleITK tests.

```
cd SimpleITK-build/SimpleITK-build
test .
```

On Windows you will need to specify configuration. Typically that would be the Release configuration, as such:

```
cd SimpleITK-build/SimpleITK-build
test -C Release
```

8.6.5 Installation from Build Tree

Python Installation

To install a built python package into the system Python, as root run:

```
python -m pip install SimpleITK-build/Wrapping/Python
```

Preferably, a Python virtual environment is created and the distribution installed there.

A Python Wheel file (.whl) is built by the “dist” target and produced in the “Wrapping/Python/dist” directory. If you use the Superbuild with the “make” generator then issue the following command:

```
make -C SimpleITK-build dist
```

R Installation

To install a built R package:

```
cd SimpleITK-build/Wrapping/R/Packaging
R CMD INSTALL SimpleITK
```

This installs the R package “SimpleITK” in /usr/local as root or your local R installation directory.

If you work in a multi-user environment, and are considerate of your fellow users you can install the package in a local directory:

1. Create a local directory to install your R packages

```
mkdir my_R_libs
```

2. In your home directory create a file named .Renviron with the following line

```
R_LIBS_USER="/path_to/my_R_libs"
```

3. Check that the R library paths include this directory, in an R shell or from RStudio:

```
.libPaths()
```

4. install
8.7 Building SimpleITK Sphinx based documentation

SimpleITK uses Sphinx to create the documentation hosted on read-the-docs. To build this documentation we set up a Python environment with the appropriate packages.

8.7.1 Set up Sphinx Python virtual environment

The following are steps for setting up Sphinx:

1. Create a Python virtual environment ("sitkenv" is the name for the new virtual environment and its directory in this example).
   
   ```
   python -m venv sitkenv
   
   (sitkenv) $ pip install -r SimpleITK/docs/requirements.txt
   ```

2. Activate the virtual environment
   
   ```
   $ source sitkenv/bin/activate
   (sitkenv) $
   ```

3. Install Sphinx and packages using the requirements.txt (found in SimpleITK/docs directory).
   
   ```
   (sitkenv) $ pip install -r SimpleITK/docs/requirements.txt
   ```

8.7.2 Build documentation

Once the Sphinx environment is configured, build the SimpleITK documentation. From the SimpleITK/docs directory (on OSX/Linux):

```
(sitkenv) $ make html
```

Results are in the SimpleITK/docs/build/html directory.
9.1 Java

Java and SimpleITK are a natural fit. Like the bindings of other languages wrapped by SimpleITK, SimpleITK’s Java bindings have a language-specific component (traditional Jar file), and a native component (native shared library). This combination requires a little more setup, but is largely transparent to the developer.

9.1.1 Build/Install SimpleITK

For Windows, you have two options:

• Download the binary for SimpleITK
• Build the binary

For any other OS, you must build the binaries yourself.

9.1.2 Set Up Eclipse

Download Eclipse on your platform of choice. Eclipse is a commonly used integrated development environment (IDE) used for Java because it makes development, debugging and deployment streamlined.

Then, create a new project in Eclipse. Choose File -> New -> Project…, choosing Java Project in the Eclipse project wizard dialog, and name the project as you like. In this example, our project is called SimpleITK Demo. Create a new class by choosing File -> New -> Class, or simply copy the code below and paste into the project item in the Package Explorer view and Eclipse will automatically create the class and hierarchy for you.

9.1.3 GaussianExample

Here is our first class Code/GaussianExample.java:

```java
package org.itk.simple.example;

import org.itk.simple.Image;
import org.itk.simple.SimpleITK;

public class GaussianExample {
    /**
     * @param args
     */
```
public static void main(String[] args) {
    if (args.length < 2) {
        System.err.println("Usage: 'Gaussian <input> <output>'");
        System.exit(1);
    }
    System.out.println("Starting to blur " + args[0]);
    // Grab a file (there will be an error if the image is not scalar)
    Image image = SimpleITK.readImage(args[0]);
    Image output = SimpleITK.discreteGaussian(image);
    SimpleITK.writeImage(output, args[1]);
    System.out.println("Finished blurring, writing to " + args[1]);
}

If Eclipse is working as expected, you should see errors on lines 16-20. These errors occurs because we have not told Eclipse where to find SimpleITK’s jar file.

9.1.4 Add SimpleITK to the Build Path

Right click on the project in the Package Explorer view and choose Build Path –> Configure Build Path…

In the Properties dialog, click on Java Build Path and Add External JARs… then navigate to the SimpleITK jar file. When selected, click the down arrow to expose the options for the jar.

The three options of interest are: Source attachment, Javadoc location and Native library location. The Source attachment specifies where the source code for the SimpleITK jar file resides. In our case, it is distributed as simpleitk-
source.x.x.x.jar where x.x.x is the version number of SimpleITK. The source attachment is useful for debugging the SimpleITK library, if necessary, because it allows the debugger to step through classes provided in the SimpleITK jar file. This setting is optional.

The Javadoc location is also optional, but extremely helpful in developing with Java. Having Javadoc available provides Eclipse with in-line documentation for each function, if provided. We highly recommend supplying the Javadoc location to Eclipse.

The last option, Native library location is required. Because SimpleITK is a C++ library, all functionality is provided through the JNI (Java Native Interface) specification. When the SimpleITK classes are loaded, a static block loads the native library to provide all the functionality to Java. This option tells Eclipse where to search for the library; without it a UnsatisfiedLinkError is thrown:

```
Exception in thread "main" java.lang.UnsatisfiedLinkError: no SimpleITKJava in java.
  ...library.path
    at java.lang.ClassLoader.loadLibrary(ClassLoader.java:1758)
    at java.lang.Runtime.loadLibrary0(Runtime.java:823)
    at java.lang.System.loadLibrary(System.java:1045)
    at org.itk.simple.SimpleITKJNI.<clinit>(SimpleITKJNI.java:62)
    at org.itk.simple.SimpleITK.readImage(SimpleITK.java:33)
    at org.itk.simple.example.GaussianExample.main(GaussianExample.java:19)
```

Set the Native library location to the directory containing the platform specific JNI library, i.e. libSimpleITKJava.jnilib on Mac OSX, libSimpleITKJava.so on Linux and SimpleITKJava.dll on Windows. After providing the library location, our example code runs correctly. When running this example from the command line, the native library location needs to be specified to the JVM, e.g. -Djava.library.path=/path/to/SimpleITKRuntime.
9.1.5 SimpleITK Java Conventions

The SimpleITK Java bindings closely follow the C++ conventions, i.e. each class contains the public member functions. However, the functional interface is handled differently in Java. In particular, every static Java function must belong to a class, unlike C++. In SimpleITK, the functional interface is contained in a class called `org.itk.simple.SimpleITK`. This class contains the functional interfaces as static member functions, i.e. `org.itk.simple.SimpleITK.readImage` as shown in `GaussianExample`. The naming conventions for all SimpleITK classes follows the C++ conventions, but member functions and the function interface follow the Java conventions of using CamelCase with the first letter lowercase. In Java, the C++ function `itk::simple::ReadImage` becomes `org.itk.simple.SimpleITK.readImage`.

9.2 C#

This guide will show how to set up a C# project in Microsoft Visual Studio 2017 using SimpleITK binaries. The same steps should apply for all other versions of Visual Studio.

9.2.1 Building SimpleITK

For Windows, you have two options:

- **Download** the binary for SimpleITK in your Documents
- **Build** the binary

To build the SimpleITK library manually:

1. Open the `SimpleITK-1.1.0-CSharp-win64-x64` folder in your Documents.
2. Right-click on the `SimpleITK-1.1.0-CSharp-win64-x64` folder and select **Properties**.
3. In the **Properties** window, go to the **Configuration Properties** tab and select **Build**.
4. Change the **Target Platform** to **x64**.
5. Click **Apply** and **OK**.

To add the SimpleITK library to your project:

1. In Visual Studio, go to **File** > **Add** > **Existing Item**.
2. Select the **SimpleITK-1.1.0-CSharp-win64-x64** folder in your Documents.
3. Select all the `.dll` files and click **Add**.
4. Right-click on the `SimpleITK-1.1.0-CSharp-win64-x64` folder and select **Properties**.
5. In the **Properties** window, go to the **Configuration Properties** tab and select **Build**.
6. Change the **Target Platform** to **x64**.
7. Click **Apply** and **OK**.

Now you can start using SimpleITK in your C# project.
For any other OS, you must build the binaries yourself.

### 9.2.2 Set Up Visual Studio

Download [Visual Studio](https://www.visualstudio.com) if you don’t have it.

Then, create a new project in Visual Studio. Choose `File -> New -> Project…`, then select “Visual C#” and “Console App”.

![New Project](image)

### 9.2.3 Select Architecture

The SimpleITK binary only supports a single architecture platform. Your project should be configured to match that same platform. By default, in the Toolbar “Debug” is selected for the Solution Configuration and “Any CPU” is selected for the Solution Platform, this needs to be changed.

- Bring up the “Configuration Manager” dialog from the menu `BUILD -> Configuration Manger…`
- The architecture of the SimpleITK binary needs to be added, and the “Any CPU” architecture needs to be removed. This needs to be done for both the “Active solution platforms” and the “Platform”.

---

9.2. C#
9.2.4 Add Managed Library

• From the menu bar select PROJECT->Add Reference… to bring up the Reference Manager. Click Browse… and navigate the file system to unzip “SimpleITKSharpManaged.dll” from the binary download, then click OK to add.

9.2.5 Add Native Library

• From the menu bar select PROJECT->Add Existing Item… Select “Executable Files” for the extension type. Then navigate the file system to the unzipped “SimpleITKSharpNative.dll” file from the binary download. IMPORTANT in the “Add” button’s pull down menu select “Add As Link”.

• In the Solution Explorer right click on the “SimpleITKSharpNative.dll”, and select “Properties”.

• Then for “Build Action”, choose “Content”, and “Copy to OutputDirectory” choose “Copy always”.

9.2.6 Building an Example

Now that we have configured the project, let up copy a basic SimpleITK example to compile and run. The Simple Gaussian in C# is a simple one to test our configuration. This can just be copied and pasted into the code editor.

Then click Build -> Build Solution. Assuming you have followed all of the steps thus far, you should have an executable you can run from the command line or from Visual Studio by adding command line arguments in Project -> ConsoleApp1 Properties… -> Debug.
Chapter 9. Setting Up Eclipse and Visual Studio
Whether you are a student at the beginning of a research career in biomedical image analysis or a seasoned veteran, you will likely find attending a SimpleITK tutorial beneficial. These tutorials will shorten the time it takes you to master SimpleITK, with all of the material (code, data, presentations) provided using permissive licenses. After the tutorial, you can readily use the code in your research or go on to use it in your own teaching activities. Additionally, attending a tutorial allows you to directly interact with the SimpleITK team. This is your opportunity to request specific features, and get advice on how to best utilize SimpleITK for your research needs.

While SimpleITK supports eight programming languages, the lingua franca of the biomedical data science community is either Python or R, hence most tutorials utilize Jupyter notebooks in one or both of these languages.

SimpleITK tutorials and courses have been given in the following venues:
10.1 Virtual

SimpleITK: A Simplified Path to Insight [git repository].

10.2 Upcoming (in person)

10.3 Past (in person)

Canceled by ISBI organizers due to COVID-19

- International Symposium on Biomedical Imaging (ISBI) 2020 Tutorial, Iowa City IA, USA: SimpleITK: image analysis for all levels of programming expertise [git repository].

- SPIE Medical Imaging 2019 Course, San Diego CA, USA: SimpleITK Jupyter Notebooks: Biomedical Image Analysis in Python [git repository].

- IEEE International Symposium on Biomedical Imaging (ISBI) 2018 Tutorial, Washington DC, USA: Biomedical Image Analysis in Python and R using SimpleITK Jupyter Notebooks [git repository].

- SPIE Medical Imaging 2018 Course, Houston TX, USA: SimpleITK Jupyter Notebooks: Biomedical Image Analysis in Python [git repository].

- The International Symposium on Biomedical Imaging (ISBI) 2016, Prague, Czech republic: SimpleITK: An Interactive, Python-Based Introduction to SimpleITK with the Insight Segmentation and Registration Toolkit (ITK).

- SPIE Medical Imaging 2016, San Diego, USA: ITK in Biomedical Research and Commercial Applications [git repository, additional presentations].

- ImageJ User & Developer Conference 2015, Madison, WI, USA: an introductory tutorial in Python [git repository].

- Medical Image Computing and Computer Assisted Intervention (MICCAI) 2011, Toronto, Canada: a general tutorial on SimpleITK [pdf of presentation, git repository].
CHAPTER
ELEVEN

FREQUENTLY ASKED QUESTIONS

This page hosts frequently asked questions about SimpleITK, and their answers.

11.1 General

11.1.1 Does SimpleITK offer all the functionality as the C++ ITK?

SimpleITK supports most ITK image filters (see list) and the IO and registration frameworks. It exposes fewer settings than ITK, hence the Simple in the name. The main ITK elements omitted from SimpleITK are the pipeline architecture, spatial objects framework, point sets, and the mesh framework.

11.2 Installation

11.2.1 I am using the binary distribution of SimpleITK for Anaconda, why do I get an error about libpng?

```
ImportError: dlopen(_SimpleITK.so, 2): Library not loaded: @rpath/libpng15.15.dylib Referenced from: .../lib/python2.7/site-packages/SimpleITK/_SimpleITK.so Reason: image not found
```

This type of error can occur if a library SimpleITK depends on can not be found. It may be that the version of the dependent library has changed in the Python environment and is no longer compatible. One solution is to create a environment.yml file with all the packages required for a project, then create a new environment:

```
conda env create -f environment.yml
```

11.2.2 Why am I getting “ModuleNotFoundError: No module named ‘_SimpleITK’” when importing SimpleITK on Windows?

```
Traceback (most recent call last):
  File “C:Python37libsite-packagesSimpleITKSimpleITK.py”, line 14, in swig_import_helper
    return importlib.import_module(mname) ... File “<frozen importlib._bootstrap>”, line 219, in
    _call_with_frames_removed ImportError: DLL load failed: The specified module could not be found.
```

The above error occurs on Microsoft windows when system libraries SimpleITK depends on are not available on the system. This issue can be resolved by installing the appropriate Redistributable for Visual Studio package.
11.2.3 Why am I getting “DllNotFoundException: Unable to load DLL ‘SimpleITKSharpNative’” when running a CSharp application on Windows?

This error message can be the result of an incomplete installation of SimpleITK in the CSharp application. Below is the complete error message that can result:

```csharp
System.TypeInitializationException: 'The type initializer for 'itk.simple.SimpleITKPINVOKE' threw an exception.'

TypeInitializationException: The type initializer for 'SWIGExceptionHelper' threw an exception.

DllNotFoundException: Unable to load DLL 'SimpleITKSharpNative': The specified module could not be found. (Exception from HRESULT: 0x8007007E)
```

The application is missing the SimpleITK dynamically loaded library (DLL). To fix this problem, follow the instructions in the Add Native Library section of the SimpleITK Visual Studio/C# build instructions.

11.3 How to Use

11.3.1 What filters are currently available in SimpleITK?

There are nearly 300 ITK image filters wrapped in SimpleITK. We have a list of filters accompanied by a brief description. Additionally the Doxygen can be examined to determine the availability of a filter.

11.3.2 What image file formats can SimpleITK read?

See here.

11.3.3 How do I read a RAW image into SimpleITK?

In general raw image files are missing information. They do not contain the necessary header information to describe the basic size and type for the data, so this format is intrinsically deficient. The RawImageIO class is not available in SimpleITK so there is no direct way to programmatically hard code this header information. The suggested way is to create a Meta image header file (*.mhd) which references the raw data file and describes the size and type of the data. The documentation on how to write a Meta image header can be found here.

The following is a sample Meta image header file, perhaps of name sample.mhd:

```plaintext
ObjectType = Image
NDims = 3
DimSize = 256 256 64
ElementType = MET_USHORT
ElementDataFile = image.raw (this tag must be last in a MetaImageHeader)
```

An example implementing this approach is available here here.
11.3.4 Why does my image appear to be empty / all black / blank when visualized?

There are two possible reasons for this:

1. The image is indeed empty. This is rarely the case, and indicates that there is something incorrect with the code, will require debugging.

2. The image contains very low values (1, 2, 3...). This is very common with segmentation and binary mask images. What you are experiencing is an issue with data visualization, not with the data itself. The code below illustrates the difference, and shows how to quickly visualize such images using the existing SimpleITK functionality.

```python
import SimpleITK as sitk

# Create segmentation image
segmentation_image = sitk.Image([128, 128], sitk.sitkUInt8)
segmentation_image[40:50, 20:120] = 1
segmentation_image[50:60, 20:120] = 2
segmentation_image[60:70, 20:120] = 3

# When visualized with Fiji, image looks all black. To see the data
# change the display settings Image->Adjust->Brightness/Contrast.
sitk.Show(segmentation_image)

# For quick visualization, convert to float and add
# 255 so that the data is immediately visible in Fiji.
sitk.Show(sitk.Cast(segmentation_image, sitk.sitkFloat32) + 255)
```

11.3.5 Why isn’t Fiji or ImageJ found by the Show function (RuntimeError: Exception thrown...)?

The SimpleITK Show function expects the Fiji or ImageJ application to be installed in specific locations. The recommended installation locations are:

- On Windows: in your user directory (e.g. C:\Users\your_user_name\Fiji.app).
- On Linux: in ~/.bin.
- On Mac: in /Applications or ~/Applications.

To see the locations where the function is searching set Show’s debugOn flag.

In Python:

```python
sitk.Show(image, debugOn=True)
```

In R:

```r
Show(image, "file_name", TRUE)
```

Show is a functional interface to the ImageViewer class. Other viewing applications can be configured using an ImageViewer object, as described in the next section.
11.3.6 Can I use another image file viewer beside Fiji?

The ImageViewer class allows a user to configure what application SimpleITK uses to display images. An ImageViewer object displays an image via the Execute method.

The default display application for all image types is Fiji. To override Fiji with some other application, use the ImageViewer::SetCommand method. For example in Python on Linux systems, using ImageMagick’s display program would look like this:

```python
import SimpleITK as sitk
viewer = sitk.ImageViewer()
viewer.SetFileExtension('.png')
viewer.SetCommand('/usr/bin/display')
```

By default when ImageViewer::Execute is called, it writes out a temporary image in Nifti format then launches Fiji. If the viewing application has been changed to one that does not support Nifti, the file format of the temporary file can be overridden using the ImageViewer::SetFileExtension method. In the above example, we use PNG, a format ImageMagick does support, unlike Nifti.

Use of a file extension unsupported by ITK results in an error message. For the supported image formats, see the ITK Image IO Filters.

More details into ImageViewer configuration can be found in the ImageViewer class documentation.

11.3.7 How can I use 3D Slicer to view my images?

3D Slicer is a very powerful and popular application for visualization and medical image computing. An ImageViewer object can be configured to use Slicer instead of SimpleITK’s default viewer, Fiji. The following are examples of how to configure an ImageViewer object in Python for Mac OS X, Linux and Windows to use Slicer.

Mac OS X

```python
import SimpleITK as sitk
viewer = sitk.ImageViewer()
viewer.SetCommand('/Applications/Slicer.app/Contents/MacOS/Slicer')
```

Linux

```python
import SimpleITK as sitk
viewer = sitk.ImageViewer()
viewer.SetCommand('Slicer')
```

Windows

```python
import SimpleITK as sitk
viewer = sitk.ImageViewer()
viewer.SetCommand('c:\Program Files\Slicer 4.10.2\Slicer')
```

The call to SetCommand should be modified to point to wherever the Slicer executable is installed.
11.4 Wrapping

11.4.1 Python

Why should I use a virtual environment?

Before installing SimpleITK we highly recommend creating a virtual environment into which the package can be installed. Note that different Python versions and distributions have different programs for creating and managing virtual environments.

The use of a virtual environment allows a user to elegantly deal with package compatibility issues, to quote The Hitchhiker’s Guide to Python!:

A Virtual Environment is a tool to keep the dependencies required by different projects in separate places, by creating virtual Python environments for them. It solves the “Project X depends on version 1.x but, Project Y needs 4.x” dilemma, and keeps your global site-packages directory clean and manageable.

Programs for creating virtual environments include venv for generic Python distributions, conda for the anaconda distribution, and canopy_cli for the canopy distribution.

Are the Python Wheels compatible with Enthought Canopy Distribution?

The Generic Python Wheels frequently seem to work with the Enthought Canopy Python distribution. However, we recommend compiling SimpleITK explicitly against this Python distribution to ensure compatibility.

11.4.2 Tcl

11.4.3 Java

11.4.4 C#

11.4.5 R

11.5 Compilation

11.5.1 Is my compiler supported?

SimpleITK uses advanced C++ meta-programming to instantiate ITK’s Images and Filters. SimpleITK is developed to require the C++11 standard.

In practice the list of compilers actively supported are those that are used for continuous testing and integration. These can be seen on the SimpleITK dashboard. We welcome user contributions to the nightly dashboard to expand the list of these compilers and contributions to fix additional compilation problems.
Noted Problems

- Microsoft compilers before Visual Studio 14 (2015) have had memory limitation issues.

11.5.2 Are 32-bits architectures supported?

While 32-bit binaries are no longer pre-compiled, the Intel 32-architecture are still tested to help ensure robustness of the toolkit. Contributions and bug reports to support additional architectures are welcomed.

11.5.3 Why does the Superbuild fail compiling PCRE on Mac OS X?

If the Xcode command line tools are not properly set up on OS X, PCRE could fail to build in the Superbuild process with messages such as:

```
checking whether we are cross compiling... configure: error: in `/your/build/path/
  SimpleITK/PCRE-prefix/src/PCRE-build'
configure: error: cannot run C compiled programs.
If you meant to cross compile, use `--host'.
See `config.log' for more details
```

To install the command line developer tools enter the following:
```
xcode-select --install
```

To reset the default command line tools path:
```
xcode-select --reset
```

11.5.4 What Configurations on Windows are Supported For Building?

We recommend using at least Microsoft Visual Studio 15 (2017) with MSVC v140 toolset.

11.5.5 Path Length Issues on Windows

The location of the build and source directories on Windows can cause the build to fail. By default, Windows does not allow path lengths longer than 260 characters.

See Windows Path Length for more information.

11.5.6 Where is the Test Data?

The testing data is not stored in the SimpleITK repository or as part of the source code. It is mirrored on several data repositories on the web.

If the source code was obtained from the git repository, the test data should be downloaded as part of the build process via the CMake ExternalData module.

A tar-ball of the “SimpleITKData” can be downloaded for a release from the GitHub Assets, which contains the external data. It should populate the .ExternalData subdirectory of the SimpleITK source code directory when extracted.
11.5.7 Why is CMake unable to download ExternalData?

When compiling SimpleITK an error like the following may occur:

```
Object MD5=2e115fe26e435e33b0d5c022e4490567 not found at:
  checksum=2e115fe26e435e33b0d5c022e4490567&algorithm=MD5 ("Unsupported protocol")
https://simpleitk.org/SimpleITKExternalData/MD5/2e115fe26e435e33b0d5c022e4490567 ("Unsupported protocol")
  checksum=2e115fe26e435e33b0d5c022e4490567&algorithm=MD5 ("Unsupported protocol")
https://insightsoftwareconsortium.github.io/ITKTestingData/MD5/
  2e115fe26e435e33b0d5c022e4490567 ("Unsupported protocol")
https://itk.org/files/ExternalData/MD5/2e115fe26e435e33b0d5c022e4490567 ("Unsupported protocol")
```

This indicates that CMake was not compiled with SSL support. The “Unsupported protocol” message indicates that CMake can not communicate via “https”.

The solution is to use a compiled version of CMake which supports SSL. To re-build CMake with OpenSSL support, simply reconfigure CMake with the “CMAKE_USE_OPENSSL” option enabled.
With the release of SimpleITK 2.0 there are changes to the interface and to the behaviour of some methods and classes. The intent of this document is to provide guidance on how to modify code so that it is compatible with SimpleITK 2.0. This document will continue to evolve after the SimpleITK 2.0 release, consider reading the latest version. Contributions to update this document that share problems and solutions when updating to SimpleITK 2.0 are welcomed.

12.1 Interface Compatibility

These changes list API changes that cause compilation or runtime errors.

12.1.1 Composite Transforms

The `Transform::AddTransform` method was removed.

Composite transformations were previously represented using the generic `Transform` class. This class served both as a base class for all transformations and as a composite transformation. This dual purpose has been separated. Composite transformations are now represented by a dedicated class `CompositeTransform` and the associated functionality was removed from the `Transform` class.

<table>
<thead>
<tr>
<th>1.x</th>
<th>2.x</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>tx = sitk.Transform()</code></td>
<td><code>tx1 = sitk.TranslationTransform(3,(1,7, -76))</code></td>
</tr>
<tr>
<td><code>tx1 = sitk.TranslationTransform(3,(1,7, -76))</code></td>
<td><code>tx2 = sitk.Euler3DTransform()</code></td>
</tr>
<tr>
<td><code>tx2 = sitk.Euler3DTransform()</code></td>
<td><code>tx = sitk.CompositeTransform([tx1, tx2])</code></td>
</tr>
<tr>
<td><code>tx.AddTransform(tx1)</code></td>
<td><code>tx1.AddTransform(tx2)</code></td>
</tr>
<tr>
<td><code>tx.AddTransform(tx2)</code></td>
<td></td>
</tr>
</tbody>
</table>

This change does effect compatibility when reading or writing `CompositeTransforms` between versions.
12.1.2 Filter's Execute Method

The Filters' `Execute` methods with filter parameters as arguments was removed. A filter object's parameters are only set via the `SetXYZ` methods. For example the `STAPLEImageFilter` class:

<table>
<thead>
<tr>
<th>1.x</th>
<th>2.x</th>
</tr>
</thead>
<tbody>
<tr>
<td>staple_filter = sitk.STAPLEImageFilter()</td>
<td>staple_filter = sitk.STAPLEImageFilter()</td>
</tr>
<tr>
<td>staple_image = staple_filter.Execute(image1, image2, image3, confidenceWeight, foregroundValue, maximumIterations)</td>
<td>staple_filter.ConfidenceWeight(confidenceWeight)</td>
</tr>
<tr>
<td>staple_filter.SetForegroundValue(foregroundValue)</td>
<td>staple_filter.SetMaximumIterations(maximumIterations)</td>
</tr>
<tr>
<td>staple_image = staple_filter.Execute([image1, image2, image3])</td>
<td>staple_image = staple_filter.Execute([image1, image2, image3])</td>
</tr>
<tr>
<td>staple_specificity = staple_filter.GetSpecificity()</td>
<td>staple_specificity = staple_filter.GetSpecificity()</td>
</tr>
</tbody>
</table>

Alternatively, the procedural method could be used if no measurements or side effects on the object are needed.

12.1.3 Morphology Radius

The procedural interfaces for morphology filters only accept vector values for the radius parameter. Previously the procedures accepted a scalar for the radius parameter. For example, a structuring element of radius 5 used on a 3D image is specified as [5, 5, 5]:

<table>
<thead>
<tr>
<th>1.x</th>
<th>2.x</th>
</tr>
</thead>
<tbody>
<tr>
<td>seg = sitk.BinaryDilate(seg, 5)</td>
<td>seg = sitk.BinaryDilate(seg, [5]*seg. GetDimension())</td>
</tr>
</tbody>
</table>

The following is a list of procedures affected by this change:

- `BinaryClosingByReconstruction`
- `BinaryDilate`
- `BinaryErode`
- `BinaryMorphologicalClosing`
- `BinaryMorphologicalOpening`
- `BinaryOpeningByReconstruction`
- `BlackTopHat`
- `ClosingByReconstruction`
- `DilateObjectMorphology`
• ErodeObjectMorphology
• GrayscaleDilate
• GrayscaleErode
• GrayscaleMorphologicalClosing
• GrayscaleMorphologicalOpening
• MorphologicalGradient
• OpeningByReconstruction
• WhiteTopHat

12.1.4 FastMarchingImageFilter

The `FastMarchingImageFilter::AddTrialPoints` and `FastMarchingImageFilter::ClearTrialPoints` methods were removed. The `SetTrialPoints` method can be used instead to set the whole list of trial points.

12.2 Behavior Changes

12.2.1 ITKv5

SimpleITK 2.0 uses ITK version 5.0. This major version change to ITK includes numerous changes to the usage and behavior of ITK. The ITK v5 Migration Guide contains valuable information documenting changes.

12.2.2 Show Environment Variables

The environment variables related to the `Show` method are only checked once. The `Show` method is a wrapper for the `ImageViewer` class, changing the behavior from SimpleITK 1.0. The `SITK_SHOW_EXTENSION` and `SITK_SHOW_COMMAND` environment variables if defined initialize the corresponding global defaults only the first time accessed. The environment variables `SITK_COLOR_COMMAND` and `SITK_SHOW_3D_COMMAND` were removed as the `ImageViewer` class allows for direct configuration of the command.

12.2.3 Images

Images support sub-image left assignment of constants and matching image regions.

\[
\text{img}[0:10,5:15] = 128 \\
\text{img}[5:10,10:15] = \text{img2}[0:5,5:10]
\]
12.2.4 DICOM MOCHOROME1

Changes to DICOM reading, due to SimpleITK’s move from ITK 4.x to 5.x. Photometric interpretation, tag 0028|0004, is now taken into account when reading the image.

1. MOCHOROME1: previously intensity values loaded as is, now they are inverted. Code that previously inverted the intensities explicitly needs to be removed.

2. Color images (e.g. YBR_FULL_422): Previously channels loaded as is, now they are converted to RGB. If previous code used the photometric interpretation tag value to perform color space conversions outside of SimpleITK it will need to be modified. For example, previously the first channel for an image with photometric interpretation of YBR_FULL was luminance and could be used as the grayscale version of the image. Now all three channels are used to compute the image luminance:

<table>
<thead>
<tr>
<th>1.x</th>
<th>2.x</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>image = sitk.ReadImage(file_name)</code></td>
<td><code>image = sitk.ReadImage(file_name)</code></td>
</tr>
<tr>
<td>grayscale_image = sitk.</td>
<td>grayscale_image = 0.299 * sitk.</td>
</tr>
<tr>
<td>VectorIndexSelectionCast(image, 0)</td>
<td>VectorIndexSelectionCast(image, 0, sitk.</td>
</tr>
<tr>
<td>sitk.</td>
<td>sitk.</td>
</tr>
<tr>
<td>VectorIndexSelectionCast(image, 0, sitk. sitkFloat32)</td>
<td>VectorIndexSelectionCast(image, 1, sitk. sitkFloat32)</td>
</tr>
<tr>
<td>0.299 * sitk.</td>
<td>0.587 * sitk.</td>
</tr>
<tr>
<td>VectorIndexSelectionCast(image, 1, sitk. sitkFloat32)</td>
<td>VectorIndexSelectionCast(image, 2, sitk. sitkFloat32)</td>
</tr>
<tr>
<td>0.299 * sitk.</td>
<td>0.114 * sitk.</td>
</tr>
<tr>
<td>VectorIndexSelectionCast(image, 2, sitk. sitkFloat32)</td>
<td>VectorIndexSelectionCast(image, 0, sitk.</td>
</tr>
<tr>
<td>grayscale_image = sitk.</td>
<td>grayscale_image = sitk.</td>
</tr>
<tr>
<td>Cast(grayscale_image)</td>
<td>RescaleIntensity(grayscale_image))</td>
</tr>
</tbody>
</table>

12.2.5 Python Installation

The Python installation procedure to use setup.py changed. To install see the updated Python Installation documentation.
12.2.6 Multi-threading

The upgrade to ITKv5 contains a major refactoring of ITK’s threading model. Details on the behavior of the new default PoolMultiThreader can be found in the ITK v5 Multi-Threading Section.

The SimpleITK ProcessObject class contains the methods to configure the ITK Threader used and the number of threads and number of work units used for an algorithm.

12.2.7 Registration Smoothing

Results from the registration framework may change due to the Gaussian smoothing algorithm changing from the DiscreteGaussianImageFilter to the SmoothingRecursiveGaussianImageFilter.
13.1 Image Filter Templates ReadMe

This document outlines the system used to generate SimpleITK files using json data files in conjunction with the template .h and .cxx files.

13.2 Overview

In order to create a uniform body of image filters, we use an automated code generation system to wrap existing ITK filters into SimpleITK filters. The development process consists of writing a JSON data file which specifies the information needed to fill in the fields of the template file. During compilation, all of the .json files are parsed using a lua template engine which fills in the appropriate template file from the provided fields. This ReadMe provides a detailed description of the fields that can be used in the json data files and what effect each field has on the resulting image filter. When writing your own json file, it should be saved in: SimpleITK_SOURCE_DIR/Code/$FILTER_DIR/json

Here $FILTER_DIR is the directory in which the code for the generated filter should live. For simple filters this is the “BasicFilters” directory.

13.3 JSON File Structure

JSON (JavaScript Object Notation) is a simple text formatting system used to specify data values. A full description of the specification can be found at http://www.json.org/. For the purposes of SimpleITK, a json file consists of a single data object (denoted by {}) which contains several string : value pairs (here value may be a list denoted by []) and sub-objects. Here is an example from LaplacianRecursiveGaussian:

```json
{
    "name" : "LaplacianRecursiveGaussianImageFilter",
    "template_code_filename" : "ImageFilter",
    "template_test_filename" : "ImageFilter",
    "doc" : "",
    "number_of_inputs" : 1,
    "pixel_types" : "BasicPixelIDTypeList",
    "output_pixel_type" : "float",
    "members" : [
        {
            "name" : "Sigma",
            "type" : "double",
            "default" : "1.0",
```
In this example, we see that all pairs must use a string as the key, but may have any valid type as the value (string - “Abs”, number - 1, list - [], object - {}).
13.3.1 Fields For All Templates

This section describes the minimal set of fields required to wrap an ITK filter into SimpleITK.

13.3.2 Top Level Fields

- **name**: (string) This must be the name of the ITK filter.

- **template_code_filename**: (string) Which of the template files should be used to generate the filter. Choices are: “ImageFilter”, “RegionGrowingImageFilter”, “StructuringElementImageFilter”, “LevelSetImageFilter”, “MathematicalMorphologyImageFilter”

- **template_test_filename**: (string) Which of the template files should be used to generate the test for this filter. Choices are: “ImageFilter”, “RegionGrowingImageFilter”

- **number_of_inputs**: (integer) How many input images are used for this filter. Currently, the template system only supports filters with 1 or 2 input images

- **briefdescription**: (string) Brief description of the class (Doxygen format). This string is automatically generated by the Utilities/BuildDocs and Utilities/GenerateDocumentation.groovy scripts. If no corresponding ITK class exists, this field will not be modified. This field is maintained with the JSONDocUpdate.sh script.

- **detaileddescription**: (string) More detailed description of the class (Doxygen format). This string is automatically generated by the Utilities/BuildDocs and Utilities/GenerateDocumentation.groovy scripts. If no corresponding ITK class exists, this field will not be modified. This field is maintained with the JSONDocUpdate.sh script.

- **pixel_types**: (string) Which of the pixel type lists should be supported for this filter. The type lists are defined in sitkPixelIDTypeLists.h

- **members**: (list) This list specifies all member variables that should be accessible to the user with a Get/Set mechanism and should be part of the Execute signature for the filter. Each entry in the list must be an object

- **tests**: (list) This list specifies all automatic tests that should be generated for the filter. Each entry in the list must be an object. If no tests are specified, a test will be generated that fails with the message that a test must be written for the filter

- **itk_module**: (string) A string naming the ITK module the filter originates from. If the ITK installation used for building SimpleITK does not have this named module then the filter will be omitted in SimpleITK. This field is maintained JSONUpdateITKModules.py script.

- **itk_group**: (string) A string naming the ITK group the ITK filter originates.

- **[OPTIONAL] include_files**: (list) This list of strings specifies additional header files to include in the cxx file for this filter.

- **[OPTIONAL] custom_set_input**: (string) Code which is used to set input or multiple inputs to the filter. This overrides the standard setting of the inputs.

- **[OPTIONAL] output_pixel_type**: (string) String representing the specific pixel type to use for the output image of the filter.

- **[OPTIONAL] filter_type**: (string) Explicitly sets the FilterType used. This method overrides additional_template_types. Useful typedefs are InputImageType, and OutputImageType.

- **[OPTIONAL] public_declarations**: (string) Any c++ code written in this field will be placed into the public section of the filter’s header file

- **[OPTIONAL] additional_template_types**: (list) The standard ITK image filter template signature is:
Some filters require additional template types between the list of input image types and the output image type such as the input type of a constant. This list allows these additional parameters to be added so that the template signature looks like:

```
<InputImageType, (if 2 inputs)InputImageType, OutputImageType)>
```

Each type in the list is specified by an object with a only a `type` field which is a string specifying the type to be used.

- **[OPTIONAL] custom methods**: (list) This is a list of objects specifying custom methods that should be added to the filter. The fields required for a custom method are:
  - `doc`: (string) Documentation for this custom method
  - `name`: (string) The name of the method
  - `return_type`: (string) the return type of the method
  - **[OPTIONAL] parameters**: (list) A list of parameters for the method. Each method is specified by an object with the following fields:
    - `type`: (string) The parameter’s type
    - `var_name`: (string) The name of the variable to be used in the **body field for the custom method
  - `body`: (string) This string is the body of the method and will be placed directly into the header file. The parameter names specified with `var_name` in each of the parameter objects can be used in this body

A sample custom method might look like:

```json
{
  "name" : "Foo",
  "doc" : "This method checks if a string is equal to Foo"
  "return_type" : "bool",
  "parameters" : [
    { "type" : "std::string",
      "var_name" : "inString"
    }
  ],
  "body" : "if (!strcmp(inString.c_str(), "Foo")) { return true; } else { return false; }
}
```

This will translate to a custom method that looks like:

```cpp
/**
 * This method checks if a string is equal to Foo
 */
bool Foo( std::string inString )
{
  if (!strcmp(inString.c_str(), "Foo")) { return true; } else { return false; }
}
```
13.3.3 MemberFields Member Fields

A basic member object looks like:

```json
{
    "name" : "Sigma",
    "type" : "double",
    "default" : 1.0,
    "briefdescriptionSet" : "",
    "detaileddescriptionSet" : "Define which normalization factor will be used for the Gaussian\n\nsee RecursiveGaussianImageFilter::SetNormalizeAcrossScale\n\n",
    "briefdescriptionGet" : "",
    "detaileddescriptionGet" : ""
}
```

- **name**: (string) The name of the member variable. A variable named “Var” will be accessible with the methods “GetVar” and “SetVar”
- **type**: (string) The c++ type for this member. If using a type contained in a certain namespace (itk::simple for example), this must be included in the type description. If the member variable is of type bool, the additional ${name}On, and ${name}Off member functions are added.
- **default**: (string or number) The default value for this member. This can be a number for numerical types or a string specifying the constructor for non-basic types (std::vector< unsigned int >() for example)
- **briefdescriptionSet/briefdescriptionGet**: (string) Brief Doxygendocumentation for this individual parameter. The two forms (Set/Get) are used for the SetMember and GetMember functions. This field is automatically generated from ITK’s Doxygen for members that mirror ITK’s members. If the member if a custom, this field will not be modified.
- **detaileddescriptionSet/detaileddescriptionGet**: (string) Detailed Doxygen documentation for this individual parameter. The two forms (Set/Get) are used for the SetMember and GetMember functions. This field is automatically generated from ITK’s Doxygen for members that mirror ITK’s members. If the member if a custom, this field will not be modified.
- **[OPTIONAL] no_set_method**: (0 or 1) If set to 1, the filter will not have a Set method for this member
- **[OPTIONAL] no_get_method**: (0 or 1) If set to 1, the filter will not have a Get method for this member
- **[OPTIONAL] no_print**: (0 or 1) If set to 1, this member will not be printed in the ToString method
- **[OPTIONAL] dim_vec**: (0 or 1) If set to 1, this indicates that the member is a std::vector with size equal to the dimension of the input image. As such, it will be printed out correctly and cast to its corresponding ITK type correctly
- **[OPTIONAL] set_as_scalar**: (0 or 1) If parameter is a dim_vec, then this method adds an additional set member method to set the variable as a scalar so that all components are the same
- **[OPTIONAL] enum**: [ "enum1", "enum2", ... ] Creates a member type of the class with the array of strings with a type defined by the name of this parameter. This field makes the “type” parameter optional. It is recommended to add a test to ensure the SimpleITK values correspond to the ITK values.
- **[OPTIONAL] custom_itk_cast**: (string) Some non-basic types will require a custom cast before the corresponding ITK filter’s member can be set. This field allows the developer to specify exactly how the ITK filter sets the member’s value from the SimpleITK member’s value for example:

```json
"custom_itk_cast" :
    "filter->SetObjectValue(static_cast<typename FilterType::PixelType>(this->
    _GetObjectValue()) );"
```
13.3.4 TestFields Test Fields

A basic test object looks like:

```json
{
    "tag" : "float",
    "description" : "Dilate a float image",
    "inputA" : "Input/RA-Slice-Float.nrrd",
    "tolerance" : 0.01,
    "settings" : []
}
```

There are three ways of checking the resulting image: against a baseline image, a sha1 hash, or an md5 hash. At least one of these options must be used for each test.

- **tag**: (string) The tag to identify this specific test for the filter
- **description**: (string) Documentation to describe this specific test
- **inputA**: (string) The path from the SOURCE_DIR/Testing/Data directory for the (first) input image
- **inputA_cast**: (string) an sitkPixelIDEnum, after inputA is read the CastImageFilter is run, to covert the image type.
- [OPTIONAL] **inputB**: (string) If number_of_inputs is 2, this specifies the path from SOURCE_DIR/Testing/Data to the second input image
- [OPTIONAL] **tolerance**: (float) An error tolerance to be used when comparing the resulting image to the baseline. This is used to specify that the result should be checked against a baseline image
- [OPTIONAL] **md5hash**: (string) An md5 hash value to compare the resulting image against.
- [OPTIONAL] **sha1hash**: (string) A sha1 hash value to compare the resulting image against.
- [OPTIONAL] **settings**: (list) A list of any specific parameters values for this test. Each entry is an object of the form:

  ```json
  {
    "parameter" : "Sigma",
    "value" : 1.0
  }
  ```

**Settings Options**

- **parameter**: (string) The name of the parameter. This must match the name used when creating the filter
- **value**: (string or number) The value to assign to the parameter. This can be a number for numerical types or a string representing the constructor for more complex types
- [OPTIONAL] **python_value**: (string) For types that require a different syntax for setting the value in python, this will override the string in value
- [OPTIONAL] **lua_value**: (string) For types that require a different syntax for setting the value in lua, this will override the string in value
- [OPTIONAL] **ruby_value**: (string) For types that require a different syntax for setting the value in ruby, this will override the string in value
- [OPTIONAL] **java_value**: (string) For types that require a different syntax for setting the value in java, this will override the string in value
• [OPTIONAL] tcl_value: (string) For types that require a different syntax for setting the value in tcl, this will override the string in value

• [OPTIONAL] R_value: (string) For types that require a different syntax for setting the value in R, this will override the string in value

• [OPTIONAL] dim_vec (0 or 1): Use this flag if this parameter is a std::vector. If set to 1, the type option must also be set

• [OPTIONAL] no_get_method: (0 or 1). Set to 1 when the filter does not have a get method, so that this method will not be tested.

• [OPTIONAL] type: (string): What type the vector should be. Due to constraints with java, this should only be a primitive type. For unsigned types, the java test will convert to the signed equivalent. An example for a dim_vec parameter is:

```json
{
    "parameter" : "Size",
    "dim_vec" : 1,
    "type" : "unsigned int",
    "value" : "{1,2}"
}
```

### 13.3.5 Structure Directory Structure

The code generation system is designed to be agnostic of what subdirectory is being parsed. An example of this is BasicFilters. Here will just refer to $FILTER_DIR

There are four important subdirectories in $SimpleITK_SOURCE_DIR/Code/$FILTER_DIR:

- include: Manually written header files
- src: Manually written c++ files
- json: The input json files used to generate new filters at build time
- templates: The code templates that can be used to generate filters for this directory

When a filter is generated, it produces a .h and a .cxx file that are placed in $SimpleITK_BUILD_DIR/Code/$FILTER_DIR/include and $SimpleITK_BUILD_DIR/Code/$FILTER_DIR/src respectively.

It is also worth noting that the template files in the templates directory are comprised of a combination of c++ code, lua template expansion directives, and $(include xxx) statements. These include statements each pull in a section of template code from a file in $SimpleITK_SOURCE_DIR/ExpandTemplateGenerator/Components. These component files represent pieces of templates that are shared by multiple unique filter template types.
13.3.6 Templates Specialized Templates

The standard template is ImageFilter. This section describes the differences for each of the other template types.

- **Region Growing Image Filters**: The region growing filters support an additional set of methods for manipulating the seed list. Each region growing filter has the SetSeed, AddSeed, and ClearSeeds methods. See sitkConnectedThresholdImageFilter.h for details.

- **Kernel Image Filters**: The kernel image filters use a KernelType and have an external enum which allows the user to select which kernel to use. See sitkErodeObjectMorphologyImageFilter.h for details.

- **Dual Image Filter**: The dual image filter template’s usage should be avoided because it instantiates the combination of two pixel type lists.
14.1 Hello World

14.1.1 Overview

A “Hello World” example for SimpleITK. The example constructs a 128x128 greyscale image, draws a smiley face made of Gaussian blobs, and calls the Show function to display the image with Fiji.

14.1.2 Sample Output

Running the python code produces this image:

![Input Image](image)

Fig. 1: Input Image

14.1.3 Code

C#

```csharp
using System;
using itk.simple;

namespace itk.simple.examples {
    class HelloWorld {

        static void Main(string[] args) {
            try {

                // Create an image
```
```csharp
PixelIDValueEnum pixelType = PixelIDValueEnum.sitkUInt8;
VectorUInt32 imageSize = new VectorUInt32( new uint[] { 128, 128 } );
Image image = new Image( imageSize, pixelType );

// Create a face image
VectorDouble faceSize = new VectorDouble( new double[] { 64, 64 } );
VectorDouble faceCenter = new VectorDouble( new double[] { 64, 64 } );
Image face = SimpleITK.GaussianSource( pixelType, imageSize, faceSize, faceCenter );

// Create eye images
VectorDouble eyeSize = new VectorDouble( new double[] { 5, 5 } );
VectorDouble eye1Center = new VectorDouble( new double[] { 48, 48 } );
VectorDouble eye2Center = new VectorDouble( new double[] { 80, 48 } );
Image eye1 = SimpleITK.GaussianSource( pixelType, imageSize, eyeSize, eye1Center, 150 );
Image eye2 = SimpleITK.GaussianSource( pixelType, imageSize, eyeSize, eye2Center, 150 );

// Apply the eyes to the face
face = SimpleITK.Subtract( face, eye1 );
face = SimpleITK.Subtract( face, eye2 );
face = SimpleITK.BinaryThreshold( face, 200, 255, 255 );

// Create the mouth
VectorDouble mouthRadii = new VectorDouble( new double[] { 30, 20 } );
VectorDouble mouthCenter = new VectorDouble( new double[] { 64, 76 } );
Image mouth = SimpleITK.GaussianSource( pixelType, imageSize, mouthRadii, mouthCenter );

14.2 A Simple C++/CMake Example

Building a C++ SimpleITK application is supported by using CMake to configure the build process. CMake can generate project build systems for Unix Makefiles, Ninja, Microsoft Visual Studio, or Mac OS X code.

Here is a basic CMakeLists.txt configuration file for building a SimpleITK C++ example program.

```cmake
# A simple C++ SimpleITK example program

cmake_minimum_required(VERSION 3.16.3)

project(sitk_example)

find_package(SimpleITK)
add_executable ( sitk_example sitk_example.cxx )
target_link_libraries ( sitk_example ${SimpleITK_LIBRARIES} )
```

Here is our SimpleITK C++ example file `sitk_example.cxx`. 

Chapter 14. Examples
// This one header will include all SimpleITK filters and external objects.
#include <SimpleITK.h>
#include <sitkImageOperators.h>

// create convenient namespace alias
namespace sitk = itk::simple;

int main ( int argc, char* argv[] ) {
    sitk::PixelIDValueEnum pixelType = sitk::sitkUInt8;
    std::vector<unsigned int> imageSize ( 2, 128 );

    // Create a black image
    sitk::Image image( imageSize, pixelType );

    // Add a Gaussian blob to the image
    std::vector<double> blobSize ( 2, 64.0 );
    std::vector<double> blobCenter ( 2, 64.0 );
    image = image + sitk::GaussianSource( pixelType, imageSize, blobSize, blobCenter );

    // Write the image as a PNG file
    sitk::WriteImage(image, "blob.png" );
}

Invoking **cmake** as below in the same directory as these files will create the project buildsystem:

```
cmake .
```

### 14.2.1 Required CMake Variables

Running CMake will produce a **CMakeCache.txt** file that is the CMake configuration. Within that text file there are two variables needed to build a SimpleITK program, **SimpleITK_DIR** and **ITK_DIR**. SimpleITK_DIR needs to be set to the directory that contains the file **SimpleITKConfig.cmake**, and ITK_DIR needs to be the directory containing the file **ITKConfig.cmake**.

CMake attempts to find these files automatically, but it is unlikely to find them unless SimpleITK and ITK are installed into the system.

If SimpleITK has been built using the SuperBuild process, as described in **Building SimpleITK**, then these required directories can be found in the SuperBuild location. The SimpleITK_DIR variable should refer to the directory SimpleITK-build within the SuperBuild location, and the ITK_DIR variable should refer to the directory ITK-build in the SuperBuild location.

Here are what the settings in a CMakeCache.txt file should look like:

```
//The directory containing a CMake configuration file for ITK.
ITK_DIR:PATH=path_to_simpleitk_build_dir/ITK-build

//The directory containing a CMake configuration file for SimpleITK.
SimpleITK_DIR:PATH=path_to_simpleitk_build_dir/SimpleITK-build
```
14.2.2 Compiling using CMake

A SimpleITK program can also be compiled by running CMake. Here is the command to perform the build in the current directory:

```bash
cmake --build . --config Release
```

The ‘config’ parameter could also be set to Debug, RelWithDebInfo or MinSizeRel. On Unix-type systems Release is the default. On Windows the config must be specified explicitly. We recommend Release or MinSizeRel, since SimpleITK compiled in Debug mode is several orders of magnitude slower.

Of course traditional methods can be used to build a SimpleITK program (e.g. make on Unix, or Visual Studio on Windows), but it is often convenient to be able to use the same build command on all system types.

14.2.3 Using CMake-gui on Windows

In addition to the standard command-line CMake, a graphical-user-interface (GUI) version of CMake is also available. Here is what the CMake GUI looks like building our same example:

We have placed the files sitk_example.cxx and CMakeLists.txt in the folder `C:sitkExample`, and in CMake we have set the `source` directory to point there. Also, in CMake, we have set the `build` directory to point to `C:sitkExample-Build`.

After the user specifies the source and build directories, CMake will ask to select which compiler generator to use. The options are determined by what versions of Visual Studio are installed on the system, in this example Visual Studio 16 2019. The user must specify `x64` for the platform generator, as the default option (x86) is not supported by SimpleITK.
After clicking **Configure**, CMake will attempt to find the SimpleITK library. That can be set in the `SimpleITK_DIR` variable, as seen in the above left image. CMake is looking for the directory containing the `SimpleITKConfig.cmake` file, in our example `C:SimpleITK-buildSimpleITK-build`.

Clicking Configure again, CMake will then try to find the ITK library for the `ITK_DIR` variable (see above right). CMake is looking for the directory containing `ITKConfig.cmake`. For a SimpleITK SuperBuild, as we have done, `ITK_DIR` will be the ITK-build directory within the SuperBuild, in our case `C:SimpleITK-buildITK-build`.

Once the `SimpleITK_DIR` and `ITK_DIR` variables have been set, we can click **Generate** to create the Visual Studio project file, `ALL_BUILD.vcxproj`.
After opening `ALL_BUILD.vcxproj` in Visual Studio, the user should select a build type in Visual Studio. We recommend choosing **Release** for performance reasons. Then the user should select the **x64** build platform, not the unsupported default, **x86**. Many man-hours and cpu cycles have been wasted building SimpleITK without setting the proper platform.

### 14.3 C++ InPlace Filter Execution

#### 14.3.1 Overview

With the C++ interface of SimpleITK, some filters and image operators can run “inplace” to reduce memory usage and improve performance. When a filter is run in-place the memory allocated to the image buffer of the input image is reused for the output. Since the output buffer is not separately allocated, the peak memory usage can be reduced by 50%. The performance improvement of running an algorithm in-place comes from not only removing the cost of memory allocating but also reduced memory accessed during algorithm execution. Speedup of 1.5x are common while speedup of 10x have been observed.

The SimpleITK filters automatically run in-place with rvalue references. When a temporary result is passed as an input argument to a filter (procedure or a filter’s `Execute` method), the temporary’s buffer will be re-used for the output. Move semantics and rvalue references are an advanced C++ topic which require additional studying to fully understand the details. Procedures and `Execute` methods with rvalue references (`&&` before argument name) as the first argument support the in-place execution. The following is an example of two procedural methods which support execution in-place.
Additionally, most C++ overloaded Image numeric operators such as +, -, *, %, etc. support in-place execution.

The SimpleITK Image class supports move semantics with the constructor and assignment operator. Since the Image class also uses a copy-on-write implement for the constructors and assignment there is not a significant direct performance benefit using these operations. However, the move semantics can be useful to reduce the number of Image objects referencing the same image buffer to prevent unnecessary copies. Lastly, if a rvalue Image object is passed to a filter and that Image object’s buffer is not unique, then the image buffer will be copied before the filter is executed in-place. Generally, copying the image then executing the filter in-place is faster than executing the not in-place implementation.

The following example demonstrates implicit and explicit use of C++ rvalues to execute filter in-place for improve performance.

### 14.3.2 Code

C++

```cpp
#include "SimpleITK.h"
#include "sitkImageOperators.h"
#include <cstdlib>
#include <iostream>
namespace sitk = itk::simple;

// Rescale the intensity range for image to -1 to 1.
sitk::Image MinusOneToOne(const sitk::Image &image) {
    sitk::MinimumMaximumImageFilter mm;
    mm.Execute(image);

    const double shift = 0.5 * (mm.GetMinimum() + mm.GetMaximum());
    const double scale = (mm.GetMaximum() - mm.GetMinimum())*2.0;

    // The CastImageFilter does not operate in-place, so the image argument to
    // this function is declared as a constant reference.
    return (sitk::Cast(image, sitk::sitkFloat32) - shift) / scale;
}

// Compute the difference between two Gaussian convoluted images.
sitk::Image DifferenceOfGaussian(sitk::Image image, double sigma1, double sigma2) {
    sitk::SmoothingRecursiveGaussianImageFilter g1;
    g1.SetSigma(sigma1);
}
```

(continues on next page)
sitk::SmoothingRecursiveGaussianImageFilter g2;
g2.SetSigma(sigma2);

// This temporary is create to ensure the method is executed before image is
// moved and made invalid.
sitk::Image &&temp = g1.Execute(image);

// Both Subtract and g2 are executed in-place.
return sitk::Subtract(temp, g2.Execute(std::move(image)));

int main( int argc, char *argv[] )
{

    // Check command line parameters
    //
    if( argc < 5 )
    {
        std::cerr << "Missing Parameters " << std::endl;
        std::cerr << "Usage: " << argv[0];
        std::cerr << " inputImage outputImage lowerSigma upperSigma" << std::endl;
        return 1;
    }

    const double sigma1 = atof(argv[3]);
    const double sigma2 = atof(argv[4]);

    // Read the image
    //
sitk::ImageFileReader reader;
reader.SetFileName( std::string( argv[1] ) );

    // The below explicitly declares the image variable as a rvalue temporary.
    // Having a rvalue typed variable enables explicit declaration of temporary
    // temporary images used between filters.Alternatively this could be written
    // in one line at the sacrifice of readability and explicitness:
    // image = DifferenceOfGaussian(MinusOneToOne(reader.Execute()), sigma1, sigma2);
    //
sitk::Image &&image = reader.Execute();
image = MinusOneToOne(image);
image = DifferenceOfGaussian(image, sigma1, sigma2);

    // Set up writer
    //
```
sitk::WriteImage( image, std::string( argv[2] ) );
return 0;
}
```

# 14.4 CSharp Integration

## 14.4.1 Overview

This example illustrates how to transfer image information from and to a C# buffer.

## 14.4.2 Code

C#

```csharp
// Get and Set Buffer of SimpleITK Image

using System;
using System.Runtime.InteropServices;

using SitkImage = itk.simple.Image;
using PixelId = itk.simple.PixelIDValueEnum;

namespace itk.simple.examples
{

class Program
{
    static void Main(string[] args)
    {
        if (args.Length < 1)
        {
            Console.WriteLine("Usage: inputImage outputImage");
            return;
        }

        string inputFilename = args[0];
        string outputFilename = args[1];

        // Read input image
        SitkImage input = SimpleITK.ReadImage(inputFilename);

        // Cast so we know the the pixel type
        input = SimpleITK.Cast(input, PixelId.sitkFloat32);

        // calculate the number of pixels
        VectorUInt32 size = input.GetSize();
        int len = 1;
        for (int dim = 0; dim < input.GetDimension(); dim++)
```

(continues on next page)
{ 
    len *= (int)size[dim]; 
}

IntPtr buffer = input.GetBufferAsFloat();

// There are two ways to access the buffer:

// (1) Access the underlying buffer as a pointer in an "unsafe" block
// (note that in C# "unsafe" simply means that the compiler can not
// perform full type checking), and requires the -unsafe compiler flag
// unsafe {
//    float* bufferPtr = (float*)buffer.ToPointer();
//    // Now the byte pointer can be accessed as per Brad's email
//    // (of course this example is only a 2d single channel image):
//    // This is a 1-D array but can be access as a 3-D. Given an
//    // image of size [xS,yS,zS], you can access the image at
//    // index [x,y,z] as you wish by image[x+y*xS+z*xS*yS],
//    // so x is the fastest axis and z is the slowest.
//    for (int j = 0; j < size[1]; j++) {
//        for (int i = 0; i < size[0]; i++) {
//            float pixel = bufferPtr[i + j*size[1]];
//            // Do something with pixel here
//        }
//    }
// }
// (2) Copy the buffer to a "safe" array (i.e. a fully typed array)
// (note that this means memory is duplicated)
float[] bufferAsArray = new float[len]; // Allocates new memory the size of
Marshal.Copy(buffer, bufferAsArray, 0, len);

double total = 0.0;
for (int j = 0; j < size[1]; j++)
{
    for (int i = 0; i < size[0]; i++)
    {
        float pixel = bufferAsArray[i + j * size[1]];
        total += pixel;
    }
}

Console.WriteLine("Pixel value total: {0}", total);

// Set buffer of new SimpleITK Image from managed array.
// bufferAsArray could also have come from a bmp,png,etc...

uint width = input.GetWidth();
uint height = input.GetHeight();

SitkImage outImage = new SitkImage(width, height, PixelId.sitkFloat32);
IntPtr outImageBuffer = outImage.GetBufferAsFloat();
Marshal.Copy(bufferAsArray, 0, outImageBuffer, (int)(size[0] * size[1]));

// Write out the resulting file
outImage = SimpleITK.RescaleIntensity(outImage, 0, 255);
outImage = SimpleITK.Cast(outImage, PixelId.sitkUInt8);
SimpleITK.WriteImage(outImage, outputFilename);

14.5 DemonsRegistration1

14.5.1 Overview

This example illustrates how to use the classic Demons registration algorithm. The user supplied parameters for the algorithm are the number of iterations and the standard deviations for the Gaussian smoothing of the total displacement field. Additional methods which control regularization, total field smoothing for elastic model or update field smoothing for viscous model are available.

The underlying assumption of the demons framework is that the intensities of homologous points are equal. The example uses histogram matching to make the two images similar prior to registration. This is relevant for registration of MR images where the assumption is not valid. For other imaging modalities where the assumption is valid, such as CT, this step is not necessary. Additionally, the command design pattern is used to monitor registration progress. The resulting deformation field is written to file.

14.6 DemonsRegistration2

14.6.1 Overview

This example illustrates how to use the fast symmetric forces Demons algorithm. As the name implies, unlike the classical algorithm, the forces are symmetric.

The underlying assumption of the demons framework is that the intensities of homologous points are equal. The example uses histogram matching to make the two images similar prior to registration. This is relevant for registration of MR images where the assumption is not valid. For other imaging modalities where the assumption is valid, such as CT, this step is not necessary. Additionally, the command design pattern is used to monitor registration progress. The resulting deformation field is written to file.

14.7 Read Image Meta-Data Dictionary and Print

14.7.1 Overview

This example illustrates how to read only an image’s information and meta-data dictionary without loading the pixel content via the `ImageFileReader`. Reading an entire image potentially is memory and time intensive operation when the image is large or many files must be read. The image information and meta-data dictionary can be read without the bulk data by using the `ImageFileReader`'s object oriented interface, with use of the `ImageFileReader::ReadImageInformation` method.

While all file formats support loading image information such as size, pixel type, origin, and spacing many image types do not have a meta-data dictionary. The most common case for images with a dictionary is DICOM, but also the fields from TIFF, NIFTI, MetaIO and other file formats maybe loaded into the meta-data dictionary.

For efficiency, the default DICOM reader settings will only load public tags (even group numbers). In the example we explicitly set the reader to also load private tags (odd group numbers). For further information on DICOM data elements see the standard part 5, Data Structures and Encoding.

See also [Dicom Series Read Modify Write](#), [Dicom Series Reader](#).

### 14.8 Dicom Series Reader

#### 14.8.1 Overview

This example illustrates how to read a DICOM series into a 3D volume. Additional actions include printing some information, writing the image and possibly displaying it using the default display program via the SimpleITK Show function. The program makes several assumptions: the given directory contains at least one DICOM series, if there is more than one series the first series is read, and the default SimpleITK external viewer is installed.

See also Dicom Series Read Modify Write, Read Image Meta-Data Dictionary and Print.

#### 14.8.2 Code

C#

```csharp
using System;
using System.Diagnostics;
using itk.simple;
using sitk = itk.simple.SimpleITK;

namespace itk.simple.examples
{
    class DicomSeriesReader
    {

        static void Main(string[] args) {
            try {
                if (args.Length < 2) {
                    Console.WriteLine("Usage: DicomSeriesReader <input_directory> <output_file>");
                }
            }
        }
    }
}
```
return;
}

Console.WriteLine( "Reading Dicom directory: " + args[0] );
ImageSeriesReader reader = new ImageSeriesReader();

VectorString dicom_names = ImageSeriesReader.GetGDCMSeriesFileNames( args[0] );
reader.SetFileNames( dicom_names );

Image image = reader.Execute();

VectorUInt32 size = image.GetSize();
Console.WriteLine( "Image size: " + size[0] + " " + size[1] + " " + size[2] );

Console.WriteLine( "Writing image: " + args[1] );
ImageFileWriter writer = new ImageFileWriter();
writer.SetFileName( args[1] );
writer.Execute( image );

if (Environment.GetEnvironmentVariable("SITK_NOSHOW") == null)
    SimpleITK.Show( image, "Dicom Series" );

} catch (Exception ex) {
    Console.WriteLine( "Usage: DicomSeriesReader <input_directory> <output_file>"

    Console.WriteLine( ex );
}
}

}
14.9 Dicom Series Read Modify Write

14.9.1 Overview

This example illustrates how to read a DICOM series, modify the 3D image, and then write the result as a DICOM series.

Reading the DICOM series is a three step process: first obtain the series ID, then obtain the file names associated with the series ID, and finally use the series reader to read the images. By default the DICOM meta-data dictionary for each of the slices is not read. In this example we configure the series reader to load the meta-data dictionary including all of the private tags.

Modifying the 3D image can involve changes to its physical characteristics (spacing, direction cosines) and its intensities. In our case we only modify the intensities by blurring the image.

Writing the 3D image as a DICOM series is done by configuring the meta-data dictionary for each of the slices and then writing it in DICOM format. In our case we copy some of the meta-data from the original dictionaries which are available from the series reader. We then set some additional meta-data values to indicate that this series is derived from the original acquired data. Note that we write the intensity values as is and thus do not set the rescale slope (0028|1053), rescale intercept (0028|1052) meta-data dictionary values.

See also Read Image Meta-Data Dictionary and Print, Dicom Series Reader.

14.9.2 Code

Python

```python
import SimpleITK as sitk
import sys
import time
import os

if len(sys.argv) < 3:
    print("Usage: python " + __file__ + " <input_directory_with_DICOM_series> <output_directory>"
) 
    sys.exit(1)

# Read the original series. First obtain the series file names using the 
# image series reader.
data_directory = sys.argv[1]
series_IDs = sitk.ImageSeriesReader.GetGDCMSeriesIDs(data_directory)
if not series_IDs:
    print('ERROR: given directory "' + data_directory + '" does not contain a DICOM series.'
) 
    sys.exit(1)

series_file_names = sitk.ImageSeriesReader.GetGDCMSeriesFileNames(continues on next page)```
data_directory, series_IDs[0]
)

series_reader = sitk.ImageSeriesReader()
series_reader.SetFileNames(series_file_names)

# Configure the reader to load all of the DICOM tags (public+private):
# By default tags are not loaded (saves time).
# By default if tags are loaded, the private tags are not loaded.
# We explicitly configure the reader to load tags, including the
# private ones.
series_reader.MetaDataDictionaryArrayUpdateOn()
series_reader.LoadPrivateTagsOn()
image3D = series_reader.Execute()

# Modify the image (blurring)
filtered_image = sitk.DiscreteGaussian(image3D)

# Write the 3D image as a series
# IMPORTANT: There are many DICOM tags that need to be updated when you modify
# an original image. This is a delicate operation and requires
# knowledge of the DICOM standard. This example only modifies some.
# For a more complete list of tags that need to be modified see:
# http://gdcm.sourceforge.net/wiki/index.php/Writing_DICOM
writer = sitk.ImageFileWriter()
# Use the study/series/frame of reference information given in the meta-data
dictionary and not the automatically generated information from the file IO
writer.KeepOriginalImageUIDOn()

# Copy relevant tags from the original meta-data dictionary (private tags are
# also accessible).
tags_to_copy = [

### 14.10 Dicom Series From Array

#### 14.10.1 Overview

This example illustrates how to write a DICOM series from a numeric array and create appropriate meta-data so it can be read by DICOM viewers.

Generating an array is done using a simple random number generator for this case but can come from other sources.

Writing the 3D image as a DICOM series is done by configuring the meta-data dictionary for each of the slices and then writing it in DICOM format. In our case we generate all of the meta-data to indicate that this series is derived. If the new image has float values we need to encode this via the rescale slope (0028|1053), rescale intercept (0028|1052), and several additional meta-data dictionary values specifying how the values are stored.

See also Read Image Meta-Data Dictionary and Print, Dicom Series Reader.

14.11 Resample and Convert DICOM to Common Image Formats

14.11.1 Overview

This example illustrates the use of SimpleITK for converting a set of DICOM images to other file formats (tif, jpg, png,...). The output file format is specified by the user, and the output image width can also be specified by the user (height is determined from the width as resulting pixel sizes are required to be isotropic). Grayscale images with high dynamic range are rescaled to [0,255] before conversion to the new format. Output is written in the same location as the input image, or to a user specified output directory. An additional csv file mapping between original and converted file names is also written, either to the specified output directory or to the current working directory.

14.11.2 Code

Python

```python
import argparse
import csv
import functools
import itertools
import multiprocessing
import os
import sys
import SimpleITK as sitk

def convert_image(input_file_name, output_file_name, new_width=None):
    try:
        image_file_reader = sitk.ImageFileReader()
        # only read DICOM images
        image_file_reader.SetImageIO("GDCMImageIO")
        image_file_reader.SetFileName(input_file_name)
        image_file_reader.ReadImageInformation()
        image_size = list(image_file_reader.GetSize())
        if len(image_size) == 3 and image_size[2] == 1:
            image_size[2] = 0
        image_file_reader.SetExtractSize(image_size)
        image = image_file_reader.Execute()
        if new_width:
            original_size = image.GetSize()
            original_spacing = image.GetSpacing()
```
new_spacing = [  
    (original_size[0] - 1) * original_spacing[0] / (new_width - 1)  
] * 2

14.12 Fast Marching Segmentation

14.12.1 Overview

The fast marching method is a simple form of level-set evolution where only a positive speed term is used to govern
the differential equation. The resulting level-set contour only grows over time. Practically, this algorithm can be used
as an advanced region growing segmentation which is controlled by a speed image.

A good propagation speed image for segmentation is close to zero near object boundaries and relatively high in between.
In this example, an input feature image is smoothed with an anisotropic diffusion method, then the gradient magnitude
is used to produce an edge image. A Gaussian with a parameterized sigma is used during the gradient computation to
enable the level-set to slow down near edges. The Sigmoid filter performs a linear transform on the gradient magnitude
so that boundaries are near zero and homogeneous regions are close to one. The values for alpha and beta are provided
in the testing code. The heuristics used to estimate good values are dependent on the minimum value along a boundary
and the mean value of the gradient in the object’s region.

Lastly the fast marching filter is configured with an initial trial point and starting value. Each trial point consists of a
tuple for an image index including an optional unsigned starting seed value at the trial point. The trial points are the
starting location of the level-set. The output of the fast marching filter is a time-crossing map that indicate the time of
arrival of the propagated level-set front. We threshold the result to the region the level-set front propagated through
to form the segmented object. A graphical interface can be constructed to show the contour propagation over time,
enabling a user to select a the desired segmentation.

14.12.2 Example Run

Running the Python code with the following inputs:

main('BrainProtonDensitySlice.png', 'fastMarchingOutput.mha', 81 114 1.0 -0.5 3.0 100
110)

produces the input & output images below.
Input/Output Images

14.13 Filter Progress Reporting

14.13.1 Overview

SimpleITK has the ability to add commands or callbacks as observers of events that may occur during data processing. This feature can be used to add progress reporting to a console, to monitor the process of optimization, to abort a process, or to improve the integration of SimpleITK into Graphical User Interface event queues.

14.13.2 Events

Events are a simple enumerated type in SimpleITK, represented by the EventEnum type. More information about each event type can be found in the documentation for the enum. All SimpleITK filters, including the reading and writing ones, are derived from the ProcessObject class which has support for events. SimpleITK utilizes the native ITK event system but has simpler events and methods to add an observer or commands. The goal is to provide a simpler interface more suitable for scripting languages.

14.13.3 Commands

The command design pattern is used to allow user code to be executed when an event occurs. It is encapsulated in the Command class. The Command class provides a virtual Execute method to be overridden in derived classes. Additionally, SimpleITK provides internal reference tracking between the ProcessObject and the Command. This reference tracking allows an object to be created on the stack or dynamically allocated, without additional burden.

14.13.4 Command Directors for Wrapped Languages

SimpleITK uses SWIG’s director feature to enable wrapped languages to derive classes from the Command class. Thus a user may override the Command class’s Execute method for custom call-backs. The following languages support deriving classes from the Command class:

C#

```csharp
class MyCommand : Command {
    private ProcessObject m_ProcessObject;

    public MyCommand(ProcessObject po) {
        m_ProcessObject = po;
    }

    public override void Execute() {
        Console.WriteLine("{0} Progress: {1:0.00}", m_ProcessObject.GetName(), m_ProcessObject.GetProgress());
    }
}
```

Java

```java
class MyCommand extends Command {
    private ProcessObject m_ProcessObject;

    public MyCommand(ProcessObject po) {
        m_ProcessObject = po;
    }

    public override void Execute() {
        Console.WriteLine("{0} Progress: {1:0.00}", m_ProcessObject.GetName(), m_ProcessObject.GetProgress());
    }
}
```

(continues on next page)
public MyCommand(ProcessObject po) {
    super();
    m_ProcessObject=po;
}

public void execute() {
    double progress = m_ProcessObject.getProgress();
    System.out.format("%s Progress: %f\n", m_ProcessObject.getName(), progress);
}

class MyCommand(sitk.Command):
    def __init__(self, po):
        # required
        super(MyCommand, self).__init__()
        self.processObject = po

    def Execute(self):
        print("{}

Ruby

class MyCommand < Simpleitk::Command
    def initialize(po)
        # Explicit call to super class initializer is required to
        # initialize the SWIG director class to enable overloaded methods
        super()
        @po = po
    end

    # The Command method to be executed on the event from the filter.
    def execute
        puts "%s Progress: %0.2f" % [@po.get_name, @po.get_progress]
    end
end
14.13.5 Command Functions and Lambdas for Wrapped Languages

Not all languages are naturally object oriented, and it is often easier to simply define a callback inline with a lambda function. The following language supports inline function definitions for functions for the ProcessObject::AddCommand method:

**C++**

```cpp
writer.AddCommand(sitk::sitkStartEvent, [] {std::cout << "Writing..." << std::flush;});
writer.AddCommand(sitk::sitkEndEvent, [] {std::cout << "done" << std::endl;});
```

**Python**

```python
gaussian.AddCommand(sitk.sitkStartEvent, lambda: print("StartEvent"))
gaussian.AddCommand(sitk.sitkEndEvent, lambda: print("EndEvent"))
```

**R**

```r
gaussian$AddCommand('sitkStartEvent', function(method) {cat("StartEvent
")
}
gaussian$AddCommand('sitkEndEvent', function(method) {cat("EndEvent
")
```

14.13.6 Code

**CSharp**

```csharp
using System;
using itk.simple;

namespace itk.simple.examples {

    // [csharp director command]
    class MyCommand : Command {
        private ProcessObject m_ProcessObject;

        public MyCommand(ProcessObject po){
            m_ProcessObject = po;
        }

        public override void Execute() {
            Console.WriteLine("{0} Progress: {1:0.00}", m_ProcessObject.GetName(), m_
                ProcessObject.GetProgress());
        }
    }

    // [csharp director command]
    class FilterProgressReporting {

        static void Main(string[] args) {
            try {
                if (args.Length < 3) {
                    Console.WriteLine("Usage: {0} <input> <variance> <output>", args[0]);
                }
            }
        }
```
```cpp
return;
}

// Read input image
ImageFileReader reader = new ImageFileReader();
reader.SetFileName(args[0]);
Image image = reader.Execute();

// Execute Gaussian smoothing filter
DiscreteGaussianImageFilter filter = new DiscreteGaussianImageFilter();
filter.SetVariance(Double.Parse(args[1]));

MyCommand cmd = new MyCommand(filter);
filter.AddCommand(EventEnum.sitkProgressEvent, cmd);

image = filter.Execute(image);

// Write output image
ImageFileWriter writer = new ImageFileWriter();
writer.SetFileName(args[2]);
writer.Execute(image);

} catch (Exception ex) {
    Console.WriteLine(ex);
}
}
```

C++

```cpp
#include <SimpleITK.h>
#include <iostream>
#include <stdlib.h>
#include <iomanip>

namespace sitk = itk::simple;

class ProgressUpdate : public sitk::Command
{
public:
    ProgressUpdate(const sitk::ProcessObject &po)
```
void Execute() override {
    // stash the stream state
    std::ios state(NULL);
    state.copyfmt(std::cout);
    std::cout << std::fixed << std::setw(3) << std::setprecision(2);

    // Print the Progress "Active Measurement"
    std::cout << m_Process.GetName() << " Progress: " << m_Process.GetProgress() << std::endl;
    std::cout.copyfmt(state);
}

private:
    const sitk::ProcessObject &m_Process;
};

int main(int argc, char* argv[]) {
    if (argc < 4) {
        std::cerr << "Usage: " << argv[0] << " <input> <variance> <output>\n";
        return 1;
    }

    // Read the image file
    sitk::ImageFileReader reader;
    reader.SetFileName(std::string(argv[1]));
    sitk::Image image = reader.Execute();

    // This filters perform a gaussian blurring with sigma in physical
    // space. The output image will be of real type.
    sitk::DiscreteGaussianImageFilter gaussian;
    gaussian.SetVariance(atof(argv[2]));

    // Construct our custom command on the stack
    ProgressUpdate cmd(gaussian);

# 14.14 Image Grid Manipulation

## 14.14.1 Overview

There are numerous SimpleITK filters that have similar functions, but very important differences. The filters that will be compared are:

- **JoinSeriesImageFilter()** - Joins multiple N-D images into an (N+1)-D image
- **ComposeImageFilter()** - Combines several scalar images into a multi-component vector image
- **VectorIndexSelectionCastImageFilter()** - Extracts the selected index of the input pixel type vector (the input image pixel type must be a vector and the output a scalar). Additionally, this filter can cast the output pixel type (SetOutputPixelType method).
- **ExtractImageFilter()** - Crops an image to the selected region bounds using vectors; Collapses dimensions unless dimension is two
- **CropImageFilter()** - Similar to ExtractImageFilter(), but crops an image by an `itk::Size` at upper and lower bounds
- Image Slicing Operator - Uses slicing (`img[i:j, k:l]`) to extract a subregion of an image

All of these operations will maintain the physical location of the pixels, instead modifying the image’s metadata.

## 14.14.2 Comparisons

### Composition Filters

While `JoinSeriesImageFilter()` merges multiple images of the same pixel type in N dimensions into an image in N+1 dimensions, `ComposeImageFilter()` will combine scalar images into a vector image of the same dimension. The former is useful for connecting a series of contiguous images while the latter is more useful for merging multiple channels of the same object into one image (such as RGB).
Extraction Filters

VectorIndexSelectionCastImageFilter() will isolate a single channel in a vector image and return a scalar image. On the other hand, ExtractImageFilter() and CropImageFilter() will extract and return a subregion of an image, using an ExtractionRegion size and index and itk::Size's respectively. However, note that only the ExtractImageFilter() collapses dimensions. The image slicing operator can also serve the same purpose.

14.14.3 Code

Python

```python
#!/usr/bin/env python

import SimpleITK as sitk
import sys

if len(sys.argv) < 3:
    print("Usage: " + sys.argv[0] + " <input-1> <input-2>")
    sys.exit(1)

# Two vector images of same pixel type and dimension expected
image_1 = sitk.ReadImage(sys.argv[1])
image_2 = sitk.ReadImage(sys.argv[2])

# Join two N-D Vector images to form an (N+1)-D image
join = sitk.JoinSeriesImageFilter()
joined_image = join.Execute(image_1, image_2)

# Extract first three channels of joined image (assuming RGB)
select = sitk.VectorIndexSelectionCastImageFilter()
channel1_image = select.Execute(joined_image, 0, sitk.sitkUInt8)
channel2_image = select.Execute(joined_image, 1, sitk.sitkUInt8)
channel3_image = select.Execute(joined_image, 2, sitk.sitkUInt8)

# Recompose image (should be same as joined_image)
compose = sitk.ComposeImageFilter()
composed_image = compose.Execute(
    channel1_image, channel2_image, channel3_image
)

# Select same subregion using image slicing operator
sliced_image = composed_image[100:400, 100:400, 0]

# Select same subregion using ExtractImageFilter
extract = sitk.ExtractImageFilter()
extract.SetSize([300, 300, 0])
extract.SetIndex([100, 100, 0])
extracted_image = extract.Execute(composed_image)

# Select same sub-region using CropImageFilter (NOTE: CropImageFilter cannot
# reduce dimensions unlike ExtractImageFilter, so cropped_image is a three
```

(continues on next page)
# dimensional image with depth of 1

crop = sitk.CropImageFilter()
crop.SetLowerBoundaryCropSize([100, 100, 0])
crop.SetUpperBoundaryCropSize(
    [composed_image.GetWidth() - 400, composed_image.GetHeight() - 400, 1]
)
cropped_image = crop.Execute(composed_image)

R

# Run with:

crop$SetLowerBoundaryCropSize( list(100, 100, 0) )
crop$SetUpperBoundaryCropSize( list(composed_image$GetWidth()-400, composed_image$GetHeight()-400, 1) )
cropped_image <- crop$Execute(composed_image)

14.15 Image Registration Method 1

14.15.1 Overview

If you are not familiar with the SimpleITK registration framework we recommend that you read the registration overview before continuing with the example.

14.15.2 Example Run

Running the Python code with the following inputs:
main('BrainProtonDensitySliceBorder20.png', 'BrainProtonDensitySliceShifted13x17y.png', 'displaceMeth1.hdf5')
produces the text and images below.

Output Text

\[
\begin{align*}

### 14.16 Image Registration Method 2

#### 14.16.1 Overview

If you are not familiar with the SimpleITK registration framework we recommend that you read the registration overview before continuing with the example.
14.16.2 Example Run

Running the Python code with the following inputs:

```python
main('BrainProtonDensitySliceBorder20.png', 'BrainProtonDensitySliceShifted13x17y.png', 'displaceMeth2.hdf5')
```

produces the text and images below.

**Output Text**

```
0 = -0.49019 : (0.0028307206468947536, 0.0023491904331766162)

14.18 Image Registration Method 4

14.18.1 Overview

If you are not familiar with the SimpleITK registration framework we recommend that you read the registration overview before continuing with the example.
14.18.2 Example Run

Running the Python code with the following inputs:

```python
main('BrainProtonDensitySliceBorder20.png', 'BrainProtonDensitySliceShifted13x17y.png', 'displaceMeth4.hdf5')
```

produces the text and images below.

**Output Text**

14.19 Image Registration Optimizer Weights

If you are not familiar with the SimpleITK registration framework we recommend that you read the registration overview before continuing with the example.
14.19.1 Overview

The image registration framework allows us to disable subsets of the transformation parameters so that we can use a lower dimensional transformation. In some cases, if we have some better prior knowledge we can weigh the parameters accordingly (this is much harder to utilize to get a desired effect than disabling parameters).

In this example, we work with a 3D rigid transformation using the Euler parameterization, but we only allow rotation around the z axis. As there is no transformation that represents this subspace of rigid transformations, we use the SetOptimizerWeights method to disable rotations around the x and y axes. The order of the weights in the weights parameter matches the order of parameters returned from the transformation GetParameters method. For the Euler3DTransform the order is [angleX, angleY, angleZ, tx, ty, tz], so our weights vector is [0,0,1,1,1,1].

14.19.2 Code

Python

```python
#!/usr/bin/env python
import SimpleITK as sitk
import sys
if len(sys.argv) < 4:
    print("Usage:", sys.argv[0],
          "<fixedImageFile> <movingImageFile>",
          "<outputTransformFile>",
          )
    sys.exit(1)

14.22 Image Registration Method BSpline 3

If you are not familiar with the SimpleITK registration framework we recommend that you read the registration overview before continuing with the example.

14.22.1 Overview

This example performs registration of multi-modality images with a multi-resolution BSpline approach.

A BSplineTransform usually has a large number of parameters which increases the complexity and duration of optimizing the deformation. The multi-resolution BSpline approach initially performs the registration at a lower resolution with fewer parameters at the first level and then adapts or resamples the BSpline control points to a higher resolution at subsequent levels. This transformation adaption is done concurrently with the ImageRegistrationMethod’s multi-resolution feature. This enables the setting of the shrink factor, smoothing sigmas, sampling percentage and BSpline resolution to vary per level to efficiently solve a diverse set of registration problems.

The initial transform is the low resolution BSpline. The scaling factor of each BSpline used per level is specified with the ImageRegistration::SetInitialBSpline method’s third argument as an integer array. The first value is usually 1 and it is reasonable to double the resolution at each registration level. For this example the last resolution is 5, so that the result is comparable to the transformation from the previous example.

It can be important to monitor and observe the transform at each level or iteration. When the “inplace” option is enabled, the transform passed as the initial transform will be up to date during the registration process which enables it to be used in event commands.

14.24 Image Registration Method Exhaustive

14.24.1 Overview

This script demonstrates the use of the Exhaustive optimizer in the ImageRegistrationMethod to estimate a good initial rotation position.

Because gradient descent base optimization can get stuck in local minima, a good initial transform is critical for reasonable results. Search a reasonable space on a grid with brute force may be a reliable way to get a starting location for further optimization.

The initial translation and center of rotation for the transform is initialized based on the first principle moments of the intensities of the image. Then in either 2D or 3D a Euler transform is used to exhaustively search a grid of the rotation space at a certain step size. The resulting transform is a reasonable guess where to start further registration.

14.26 Integration with ITK

14.26.1 Overview

14.26.2 Code

```cpp
#include "SimpleITK.h"
#include "itkImage.h"
#include "itkCurvatureFlowImageFilter.h"

namespace sitk = itk::simple;

/**
 * This example shows how ITK and SimpleITK can be used together to work
 * on the same data. We use the same example application as the one presented
 * in the Segmentation/ConnectedThresholdImageFilter.cxx example, but we
 * replace the SimpleITK version of CurvatureFlowImageFilter with the
 * corresponding ITK version. While not terribly useful in this situation since
 * CurvatureFlowImageFilter is already available in SimpleITK this demonstrates
 * how ITK filters that have not been converted for SimpleITK can still be used
 * in a SimpleITK context
 */

int main( int argc, char *argv[])
{

    // Check command line parameters
    //
    if( argc < 7 )
    {
        std::cerr << "Missing Parameters " << std::endl;
        std::cerr << "Usage: " << argv[0];
        std::cerr << " inputImage outputImage lowerThreshold upperThreshold "
                  << " seedX seedY [seed2X seed2Y ... ]" << std::endl;
        return 1;
    }
```
// Read the image
//
#include <SimpleITK> //already linked with the itk library

sitk::ImageFileReader reader;
reader.SetFileName( std::string( argv[1] ) );
sitk::Image image = reader.Execute();

// Set up writer
//
sitk::ImageFileWriter writer;
writer.SetFileName( std::string( argv[2] ) );

////////
// Blur using CurvatureFlowImageFilter
//
// Here we demonstrate the use of the ITK version of CurvatureFlowImageFilter
// instead of the SimpleITK version.
////////

// First, define the type alias that correspond to the types of the input
// image. This requires foreknowledge of the data type of the input image.
//
const unsigned int Dimension = 2;
using InternalPixelType = float;
using InternalImageType = itk::Image< InternalPixelType, Dimension >;

// We must check the image dimension and the pixel type of the
// SimpleITK image match the ITK image we will cast to.
if ( image.GetDimension() != Dimension )
{
  std::cerr << "Input image is not a " << Dimension << " dimensional image as expected!" << std::endl;
  return 1;
}

// The read sitk::Image could be any pixel type. Cast the image, to
// float so we know what type we have.

sitk::CastImageFilter caster;
caster.SetOutputPixelType( sitk::sitkFloat32 );
image = caster.Execute( image );

// Extract the itk image from the SimpleITK image
//
InternalImageType::Pointer itkImage =
    dynamic_cast<InternalImageType*>( image.GetITKBase() );

//
// Always check the results of dynamic_casts
//
if ( itkImage.IsNull() )
{

    segmentationFilter.AddSeed(seed);
    std::cout << "Adding a seed at ";
    for( unsigned int j = 0; j < seed.size(); ++i )
    {
        std::cout << seed[j] << " ";
    }
    std::cout << std::endl;
}
sitk::Image outImage = segmentationFilter.Execute(blurredImage);
```

14.27 N4 Bias Field Correction

14.27.1 Overview

The N4 bias field correction algorithm is a popular method for correcting low frequency intensity non-uniformity present in MRI image data known as a bias or gain field. The method has also been successfully applied as flat-field correction in microscopy data. This method assumes a simple parametric model and does not require tissue classification.

This example demonstrates how to use the SimpleITK N4BiasFieldCorrectionImageFilter class. This filter has one required input image which is affected by a bias field we wish to correct. The primary input is required to have a “real” pixel type of either sitkFloat32 or sitkFloat64. Additionally, there is an optional “MaskImage” input which specifies which pixels are used to estimate the bias-field and suppress pixels close to zero. It is recommended that the mask image follows the common conventions for masked images, which is being of pixel type sitkUint8 and having values of 0 and 1 representing the mask. Additionally, the mask image and the main input image must occupy the same physical space to ensure pixel to pixel correspondence.

Some basic parameters for using this algorithm are parsed from the command line in this example. The shrink factor is used to reduce the size and complexity of the image. The N4 algorithm uses a multi-scale optimization approach to compute the bias field. The SetMaximumNumberOfIterations method takes an array used to set the limit of iterations per resolution level, thereby setting both the iterations and the number of scales (from the length of the array). The output of the filter is the bias corrected input image.
14.27.2 Example Run

Running the Python code with the following inputs:

```
main("BrainProtonDensitySlice.png", "N4_corrected.nrrd", 1)
```

produces the images below.

### 14.28 Reading-Gaussian Blurring-Writing

#### 14.28.1 Overview

Introductory example which demonstrates the basics of reading, filtering, and writing an image. This example works for any scalar or vector image type. It processes the image with a Gaussian blurring filter, which produces an image with floating point pixel type, then cast the output back to the input before writing the image to a file.

This example uses the object oriented (OO) interface to SimpleITK classes. The OO style produces more verbose code which clearly labels the parameters set by class member functions.

#### 14.28.2 Example Run

Running the Python code as follows:

```python
main('docs/images/BrainProtonDensitySlice.png', 2.0, 'output.png')
```

modifies the input image to the output image below.
Input/Output Images

14.29 Image Viewing

14.29.1 Overview

This example illustrates the basic image viewing capabilities provided by SimpleITK.

The focus of SimpleITK is on image analysis and not display. We therefore use an ad-hoc image viewing approach, relying on an external program. By default this is the Fiji/ImageJ program.

When using this functionality, SimpleITK writes the image to disc in a temporary location and then launches the viewer. Potential issues with this approach:

1. The external viewer program is not found. Either it is not installed, or not installed in the expected location, for details see Why isn’t Fiji or ImageJ found by the Show function (RuntimeError: Exception thrown…)?
2. Writing the image to disc fails when there isn’t enough disc space.
3. The external program cannot read the image file because it was saved in a format not supported by the program.

To control viewing you have two options:

1. Procedural approach. Use the Show function, with control primarily done via environment variable settings.
2. Object oriented approach. Use the ImageViewer class, with control via the object’s interface.

One can either set the viewing application, if you just want to change the specific viewer, or set the viewing command. The latter allows you to specify viewer specific arguments such as -z for ITK-SNAP, see below, to open in a zoomed view.

14.29.2 Code

Python

```python
import sys
import SimpleITK as sitk

grid_image = sitk.GridSource(
    outputPixelType=sitk.sitkUInt16,
    size=(512, 512),
    sigma=(0.1, 0.1),
    gridSpacing=(20.0, 20.0),
)

# Procedural interface, using the default image viewer (Fiji/ImageJ) or
# any viewer specified by the SITK_SHOW_COMMAND environment variable.
#  sitk.Show(grid_image, title="grid using Show function", debugOn=True)

# Object oriented interface:
image_viewer = sitk.ImageViewer()
```

(continues on next page)
image_viewer$SetTitle("grid using ImageViewer class")

# Use the default image viewer.
image_viewer$Execute(grid_image)

# Change viewer, and display again.
image_viewer$SetApplication("/Applications/ITK-SNAP.app/Contents/MacOS/ITK-SNAP")
image_viewer$Execute(grid_image)

# Change the viewer command, (use ITK-SNAP's -z option to open the image in zoomed mode)
image_viewer$SetCommand("/Applications/ITK-SNAP.app/Contents/MacOS/ITK-SNAP -z 2")
image_viewer$Execute(grid_image)

sys.exit(0)

R

# Run with:
#
# Rscript --vanilla ImageViewing.R
#
library(SimpleITK)

grid_image <- GridSource(outputPixelType="sitkUInt16", size=c(512,512),
                        sigma=c(0.1,0.1), gridSpacing=c(20.0,20.0))

# Procedural interface, using the default image viewer (Fiji/ImageJ) or any viewer specified by the SITK_SHOW_COMMAND environment variable.
Show(grid_image, title = "grid using Show function", debugOn = TRUE)

# Object oriented interface:
image_viewer <- ImageViewer()
image_viewer$SetTitle('grid using ImageViewer class')

# Use the default image viewer.
image_viewer$Execute(grid_image)

# Change viewer, and display again.
image_viewer$SetApplication('/Applications/ITK-SNAP.app/Contents/MacOS/ITK-SNAP')
image_viewer$Execute(grid_image)

# Change the viewer command, (use ITK-SNAP's -z option to open the image in zoomed mode)
image_viewer$SetCommand('/Applications/ITK-SNAP.app/Contents/MacOS/ITK-SNAP -z 2')
image_viewer$Execute(grid_image)
14.30 Slice by Slice Adaptive Histogram Equalization

14.30.1 Overview

Most SimpleITK filters can only operate on 2 or 3 dimensional images, with the exception of filters such as `ExtractImageFilter`, `PasteImageFilter`, `SliceImageFilter` and `JoinSeriesImageFilter`. However, SimpleITK (by default) supports up to 5 dimensional images. A high dimensional image can be processed by extracting 2 or 3 dimensional images, then either using the `JoinSeriesImageFilter` to join the sub-volumes together or the `PasteImageFilter` to copy the results back to the original image. Possible reasons include when the z direction spacing is too great, or for computation or memory efficient reasons. Additionally, it may be desired to process a volume (3d or higher) as a sequence of 2 dimensional images.

In this example, the `AdaptiveHistogramEqualizationImageFilter` is used to processes a higher dimensional image as a sequence of two dimensional images.. When the filter is run only a single X, Y cross-section of the volume.

Both the Python and the C++ examples demonstrate a reusable “decorator” to wrap the SimpleITK `AdaptiveHistogramEqualization` procedure to process the input image by 2d slices. A function decorator is a function which takes a function as an argument and returns a modified or wrapped function. The decorators are written generically, so they can work with other SimpleITK procedures or a custom procedure. The decorators wrap the procedure to accept a 2, 3, 4 or 5 dimensional image as input. The pasting approach is used to provide a memory efficient approach.

The process of extracting a slice, processing, and then pasting back to the original image is straightforward. However, to create a reusable decorator requires advanced language specific features. Additionally, to efficiently do pasting in place execution is done in C++, and sliced indexed assignment is used in Python.

14.30.2 Code

Python

```python
#!/usr/bin/env python

import SimpleITK as sitk
import sys
import itertools
from functools import wraps

def slice_by_slice_decorator(func):
    
    A function decorator which executes func on each 3D sub-volume and
    *in-place* pastes the results into the input image. The input image type
    and the output image type are required to be the same type.

    :param func: A function which take a SimpleITK Image as its first
        argument and returns an Image as results.

    :return: A decorated function.

    
    iter_dim = 2
```

(continues on next page)
@wraps(func)
def slice_by_slice(image, *args, **kwargs):
    
    dim = image.GetDimension()

    if dim <= iter_dim:
        #
        image = func(image, *args, **kwargs)
        return image

    extract_size = list(image.GetSize())

    std::cerr << "Usage: " << argv[0] << " <inputImage> <outputImage>" << std::endl;
    return 1;
  }

  sitk::Image tempImage = sitk::ReadImage(argv[1]);

  // The parameters to the filter are hard coded to simplify the example.
  float alpha = 0.3f;
  float beta = 0.3f;
  std::vector<unsigned int> radius(2, 20);

  // The return type of the function decorator is complex, so the auto type is
  // used for brevity.
  auto AdaptiveHistogramEqualization2D = makeSliceBySlice(sitk::AdaptiveHistogramEqualization);

  // Execute the decorated function.
  tempImage = AdaptiveHistogramEqualization2D(tempImage, radius, alpha, beta);

  sitk::WriteImage(tempImage, argv[2]);

  return 0;
}
```
14.31 Logging

14.31.1 Overview

SimpleITK creates debug, warning and error messages intended for display or logging. The messaging and logging are handled by a customizable class in ITK, the `OutputWindow`. The default implementation prints these messages to the standard error. A derived class could print the messages to standard out or adapt the output to fit within another logging framework. Errors in SimpleITK usually cause exceptions so any error message is unlikely. Warnings are more likely and are enabled globally by default, but can be disabled with the `ProcessObject::SetGlobalWarningDisplay` method. Debug messages are set on a per object basis with the `SetDebug` method. The default value for new objects is set by the `ProcessObject::SetGlobalDefaultDebug` method. Disabled messages are not sent to the logging handler for efficiency.

The following example illustrates how to create a custom logging handler in SimpleITK. The example derives a class from the `LoggerBase` class to customize the logging behavior. The custom logger is then set as the ITK global logging handler, and then the original logger is restored.

14.31.2 Code

Python

```python
import SimpleITK as sitk
import logging
import os

class SimpleITKLogger(sitk.LoggerBase):
    
    """
    Adapts SimpleITK messages to be handled by a Python Logger object.
    
    Allows using the logging module to control the handling of messages coming from ITK and SimpleITK. Messages such as debug and warnings are handled by objects derived from sitk.LoggerBase.
    
    The LoggerBase.SetAsGlobalITKLogger method must be called to enable SimpleITK messages to use the logger.
    
    The Python logger module adds a second layer of control for the logging level in addition to the controls already in SimpleITK.
    
    The "Debug" property of a SimpleITK object must be enabled (if available) and the support from the Python "logging flow" hierarchy to handle debug messages from a SimpleITK object.
    
    Warning messages from SimpleITK are globally disabled with ProcessObject::GlobalWarningDisplayOff.
    """

    def __init__(
        self, logger: logging.Logger = logging.getLogger("SimpleITK")
    ):"""
        Initializes with a Logger object to handle the messages emitted from
        """
        
    """

```
SimpleITK/ITK.

```python
super(SimpleITKLogger, self).__init__()
self._logger = logger

@property
def logger(self):
    return self._logger

@logger.setter
def logger(self, logger):
    self._logger = logger

def __enter__(self):
    self._old_logger = self.SetAsGlobalITKLogger()
    return self

def __exit__(self, exc_type, exc_val, exc_tb):
    self._old_logger.SetAsGlobalITKLogger()
    del self._old_logger

def DisplayText(self, s):
    # Remove newline endings from SimpleITK/ITK messages since the Python
    # logger adds during output.
    self._logger.info(s.rstrip())

def DisplayErrorText(self, s):
    self._logger.error(s.rstrip())

def DisplayWarningText(self, s):
    self._logger.warning(s.rstrip())

def DisplayGenericOutputText(self, s):
    self._logger.info(s.rstrip())

def DisplayDebugText(self, s):
    self._logger.debug(s.rstrip())
```

# Enable all debug messages for all ProcessObjects, and procedures
sitk.ProcessObject.GlobalDefaultDebugOn()

# Construct a SimpleITK logger to Python Logger adaptor
sitkLogger = SimpleITKLogger()

# Configure ITK to use the logger adaptor
sitkLogger.SetAsGlobalITKLogger()

# Configure the Python root logger, enabling debug and info level messages.
logging.basicConfig(  
    format="%(name)s (%(levelname)s): %(message)s",  
    level=logging.DEBUG
)
```python
img = sitk.GaborSource(size=[64, 64, 64], frequency=4.0 / 64)

with SimpleITKLogger(logging.getLogger("Show")) as showLogger:
  print(f"Logger name: {showLogger.GetName()}")

  if "SITK_NOSHOW" not in os.environ:
    sitk.Show(img, debugOn=True)
```

### 14.32 Advanced Image Reading

#### 14.32.1 Overview

This example illustrates advanced image reading options:

1. Querying an image for its meta-data without reading the bulk intensity data.
2. Reading a sub-region of an image.

**Querying an image for its meta-data**

In some cases you may only want to read an image’s meta-data without reading the bulk intensity data into memory. For instance, if you want to read subregions of an image and not the whole image or if you want to display image information (e.g. patient name) to a user in a GUI which then allows them to select a specific image.

**Reading an image sub-region**

In some cases you are only interested in reading a sub-region of an image. This may be due to memory constraints or if it is known that the relevant content is always in a sub region of the image. If the specific image IO used for this operation supports streaming then this will indeed only read the sub-region, otherwise the whole image is read into memory and the sub-region is returned. The IOs that support streaming are: 1. TIFFImageIO (supports a subset of encodings) 2. MetaImageIO 3. NrrdImageIO 4. HDF5ImageIO (supports a subset of encodings) 5. MRCImageIO 6. VTKImageIO (supports a subset of encodings)

#### 14.32.2 Code

**Python**

```python
import sys
import SimpleITK as sitk
import numpy as np

if len(sys.argv) < 2:
  print("Wrong number of arguments.", file=sys.stderr)
  print("Usage: " + __file__ + " image_file_name", file=sys.stderr)
```
sys.exit(1)

# Read image information without reading the bulk data.
file_reader = sitk.ImageFileReader()
file_reader.SetFileName(sys.argv[1])
file_reader.ReadImageInformation()
print(f"image size: {file_reader.GetSize()}")
print(f"image spacing: {file_reader.GetSpacing()}")

# Some files have a rich meta-data dictionary (e.g. DICOM)
for key in file_reader.GetMetaDataKeys():
    print(key + ": " + file_reader.GetMetaData(key))
print("---")

# When low on memory, we can incrementally work on sub-images. The following
# subtracts two images (ok, the same image) by reading them as multiple
# sub-images.

image1_file_name = sys.argv[1]
image2_file_name = sys.argv[1]

quit(save="no", status=0)
14.33 IO Selection for Image Reading

14.33.1 Overview

This example illustrates how to explicitly select a specific IO for image reading.

When using the default settings for the `ImageFileReader` class or the `ReadImage` function you have minimal control over the reading. That is, the specific IO mechanism is determined automatically based on the file type and the file is read into memory.

In some cases there are multiple IO classes that support reading the same image format and you do not know which one was used. For example the ‘SCIFIOImageIO’ and ‘JPEGImageIO’ both support reading JPEG images. As these are different implementations they may vary in performance and in the support of the features associated with the specific format. As a consequence, you may want or need to select one implementation over the other. Explicitly selecting the IO allows you to do so.

14.33.2 Code

C#

```csharp
using System;
using itk.simple;

namespace itk.simple.examples {
    class ImageIOSelection {
        static void Main(string[] args) {
            try {
                if (args.Length < 1) {
                    Console.WriteLine("Usage: ImageIOSelection image_input_file");
                    return;
                }

                // Find out which image IOs are supported
                ImageFileReader reader = new ImageFileReader();
                itk.simple.VectorString image_ios = reader.GetRegisteredImageIOs();
                Console.WriteLine("The supported image IOs are: ");
                for (int i = 0; i < image_ios.Count; i++) {
                    Console.Write(image_ios[i] + " ");
                }
                Console.WriteLine("--------------------");

                // Another option is to just print the reader and see which IOs are supported
                Console.WriteLine(reader.ToString());
                Console.WriteLine("--------------------");

                // Force the use of a specific IO. If the IO doesn't support reading the image type it will throw an exception.
                reader.SetImageIO("PNGImageIO");
                reader.SetFileName(args[0]);
                Image image = reader.Execute();
                Console.WriteLine("Read image: "+ args[0]);
            }
        }
    }
}
```

(continues on next page)
VectorUInt32 size = image.GetSize();
    Console.WriteLine( "Image size: " + size[0] + " " + size[1] );

} catch (Exception ex) {
    Console.WriteLine("Read failed: " + ex);
}

}}}
try {
    sitk::Image image = reader.Execute();

puts "Image size: $size"
14.34 Raw Image Reading

14.34.1 Overview

In some, hopefully rare, cases you may only have the image information in raw pixel format, a binary blob file. For example the chest x-ray dataset from the Japanese Society of Radiological Technology (JSRT).

To read such an image you are required to know three things:

1. Image size (number of pixels per dimension).
2. Pixel type (e.g. sitkUInt16).
3. The byte order (or endianness) where little endian is most common.

If the byte order is unknown since it only has two options and we can try both. The one resulting in a visually correct image is the correct byte order.

As a SimpleITK image is a spatial object, we may also need to provide its origin, spacing, and direction cosine matrix. Without explicit information we can make reasonable assumptions that often work, as shown in the code below.

14.34.2 Code

Python

```python
import argparse
import os
import tempfile
import SimpleITK as sitk

def read_raw(
    binary_file_name,
    image_size,
    sitk_pixel_type,
    image_spacing=None,
    image_origin=None,
    big_endian=False,
):  
    """
    Read a raw binary scalar image.

    Parameters
    ----------
```
binary_file_name (str): Raw, binary image file content.
image_size (tuple like): Size of image (e.g. [2048,2048])
sitk_pixel_type (SimpleITK pixel type: Pixel type of data (e.g.
sitk.sitkUInt16).
image_spacing (tuple like): Optional image spacing, if none given assumed
to be [1]*dim.
image_origin (tuple like): Optional image origin, if none given assumed to
be [0]*dim.
big_endian (bool): Optional byte order indicator, if True big endian, else
little endian.

Returns
-------
SimpleITK image or None if fails.

```python
pixel_dict = {
    sitk.sitkUInt8: "MET_UCHAR",
    sitk.sitkInt8: "MET_CHAR",
    sitk.sitkUInt16: "MET_USHORT",
    sitk.sitkInt16: "MET_SHORT",
    sitk.sitkUInt32: "MET_UINT",
    sitk.sitkInt32: "MET_INT",
    sitk.sitkUInt64: "MET_ULONG_LONG",
    sitk.sitkInt64: "MET_LONG_LONG",
    sitk.sitkFloat32: "MET_FLOAT",
    sitk.sitkFloat64: "MET_DOUBLE",
}

direction_cosine = [
    "1 0 0 1",
    "1 0 0 0 1 0 0 0 1",
    "1 0 0 0 0 1 0 0 0 0 1 0 0 0 0 1",
]
dim = len(image_size)

14.35 Java Image Buffer

This example demonstrates efficient access to the Image’s buffer in SimpleITK with Java. The SimpleITK Image class has the `java.nio.Buffer Image::getBufferAsBuffer(void)` method. The `java.nio.Buffer` class has derived types for Java’s signed integers, float, and double types. These derived buffer types are returned, when the SimpleITK Image’s pixel type is scalar, vector, or complex corresponds. Additionally, the `UInt16` types are returned as a `CharBuffer`, otherwise a `ByteBuffer` is returned. The returned buffer is the Image’s buffer and no copy has occurred. However, SimpleITK’s copy on write policies are followed, and `Image::MakeUnique` is called.

14.35.1 Overview

14.35.2 Code

```java
import org.itk.simple.Image;
import org.itk.simple.SimpleITK;
import org.itk.simple.PixelIDValueEnum;

class ImageGetSetBuffer {
    public static void main(String args[]) {
        if (args.length < 1) {
            System.out.format("Usage: ImageGetSetBuffer <input>");
            System.exit(-1);
        }

        Image image = SimpleITK.readImage(args[0]);

        // The loaded image may be of any type and number of components, so convert to…
        // float,
        // so there is a known type.
        if (image.getNumberOfComponentsPerPixel() != 1) {
            image = SimpleITK.cast(image, PixelIDValueEnum.sitkVectorFloat32);
        } else {
            image = SimpleITK.cast(image, PixelIDValueEnum.sitkFloat32);
        }

        java.nio.FloatBuffer buffer = (java.nio.FloatBuffer)image.getBufferAsBuffer();

        System.out.println(buffer.toString());
        for (int i = 0; i < 10 && buffer.hasRemaining(); ++i) {
            System.out.println(buffer.get());
        }
        buffer.rewind();
        while (buffer.hasRemaining()) {
            buffer.put(0);
        }
    }
}
```
